Lectures

ON SOME OF THE

SURGICAL ASPECTS OF GOUT AND RHEUMATISM.

Delivered at the Royal College of Surgeons, June, 1880.

By Professor HUTCHINSON, F.R.C.S.,
Senior Surgeon to the London Hospital.

Lecture III.

Mr. President and Gentlemen,—In my last lecture I endeavoured to point out some of the errors, or what appear to me to be errors, which have crept into the generally received descriptions of gout and rheumatism. Thus it is generally said that gout and rheumatism are always met with as distinct diseases, that they do not mix. I have tried to prove that they do mix and that very frequently, that they mix just like spirits and water, and in just as various proportions, and I supported my assertion with both classical and pathological evidence. Then it is said that whilst gout is most common in men, crippling rheumatism is most common in women. That gout is most common in men is true, but the other part of the statement is an error; statistics, if only based upon a sufficiently wide basis, show conclusively that crippling rheumatism is as common in men as in women.

Then it is said that gout is hereditary, but that rheumatism is not so. This also is true of gout, but the statement regarding rheumatism is an error. I have met with strong evidence of the hereditary transmission of a liability to chronic rheumatism, especially of the severe forms of what may be called crippling rheumatism, the constitutional rheumatic gout of Adams. Thus, to take my own cases first: out of 90 cases, only in 34 was there no evidence of the hereditary transmission, in 44 there was a family history of rheumatism; and here let me say that I do not mean that in all these cases the parents or grand-parents had suffered from rheumatism, but that in every case other members of the family, near relatives, had suffered from the disease; finally, there was a history both of gout and rheumatism in twelve cases. Charcot, in his annotations appended to his translation of Dr. Garrod's book, said that out of 41 cases he found evidence of *direct* transmission in 11.

Before taking Dr. Garrod's own figures, I may be allowed to say that it is very easy to confuse oneself in collecting figures on such a point as this; not only is it most important that the investigator should have no special bias, but the results will be greatly influenced by the way in which the inquiry is carried out. Thus the difference in the results obtained by two observers may be explained by the fact that one had more patience or more tact in ferreting out the facts of the patient's family history than the other. Dr. Garrod lays stress upon his conclusion that gout is hereditary whilst rheumatism is not, but to my mind his cases prove something quite different. Thus he gives the particulars of 19 cases of crippling rheumatism: this, he says, is much more common in women than in men, yet in these 19 cases the sexes are nearly equal, 8 men and 11 women. Then, in 7 of these cases there was evidence of hereditary transmission, in 2 there was no such evidence, and in 8 nothing was known about the family. Assuming that no hereditary predisposition existed in any of these 8 cases, we have a ratio of 7 hereditary cases to 10 not, a higher proportion than is given by M. Charcot's cases or by my own.

Then Dr. Garrod gives a table of gout cases, in which of course the facts as to heredity were carefully sought for, yet in only 13 cases out 33 is a family history of gout established. So that according to the evidence afforded by Dr. Garrod's cases rheumatic gout is as hereditary as gout.

Dr. Pye-Smith gave in the Guy's Hospital Reports particulars respecting 29 cases of what he calls osteo-arthritis, severe cases of rheumatic gout. There were only 8 men to 21 women; we may be sure that there was some principle of selection at work to get such a disproportion as this. In 12 out of the 29 cases no evidence of hereditary transmission could be found, in 4 there was

a history of rheumatism in the family, in 3 one of gout, and 9 could give no information as to their family.

We see, then, that statistics of this sort will vary according to the opportunities of the investigators. Senile rheumatism is frequently not hereditary, it may have been acquired by accidental circumstances; if, then, a large number of aged subjects are admitted into the table the ratio of hereditary cases will be low, but when the disease appears early in life it will generally be found to be hereditary.

My object in thus wishing to prove that rheumatism is hereditary as well as gout is partly that I may break down what has been set up as one of the chief distinctions between the two diseases, and also because it proves the existence of a rheumatic diathesis or latest proclivity to the diseases.

I had the honour last year of giving in this theatre a course of lectures on the Influence of the Nervous System on the Production of Organic Disease of different Parts of the Body, and in those lectures I gave some reasons for my belief in the probable existence of a catarrhal diathesis. I should confine the term catarrh to affections of the nasal and bronchial passages, which are brought on by exposure to cold, and should not include all diseases which are attended by a muco-purulent discharge. Exposure to cold or damp, or both, brings on an inflammation of a certain definite character in some more or less distant part of the body; the disease occurs often in the same person, one attack seems to predispose to another. It is not a blood change, but is evidently exerted through the nervous system; it attacks people in robust health, and there is often a certain periodicity about the disease, periods of immunity intervening between the attacks. Now it appears to me that the symptoms of true rheumatism are closely associated with those of the catarrhal diathesis; the patient, so to speak catches cold in his joints. The causes are the same, and there is the same periods of immunity, short or long. I have no belief in the theory that rheumatism is due to an accumulation of impurities in the blood; facts do not support it. But we know that in certain persons, exposure of the skin to cold, sleeping in damp sheets, or on damp grass, will produce it; this is especially true of acute rheumatism in young subjects. In this case, as in the catarrh, the effects are evidently reflex, though we don't know how the nervous system is influenced or what part of it.

In confirmation of this view, there is the fact that other forms of reflex irritation will produce the arthritis, as is seen in gonorrhœal rheumatism, dysenteric rheumatism, and that due to sexual disturbance in females. Of these, gonorrhœal rheumatism is the best known, but it may readily be supposed that if gonorrhœal irritation of the urethra will cause arthritic inflammation, other forms of irritation, not gonorrhœal, may also cause it; and this is actually the case. On the Continent a form of rheumatism, dependent on intestinal irritation, has been described under the name of dysenteric arthritis.

We will take gonorrhœal rheumatism first, since it is the common, and also because it is specially interesting to us as surgeons. I have collected out of my book all the cases in which irritation of the urinary organs in the male was the cause of arthritis. There are 29 such cases. The first thing that strikes one is the fact that in only four of these cases was the eye free from disease; the urethral irritation not only caused deranged nutrition of the joints, but of the eye also. Next, we find that the disease does not occur at random, but that a pre-existing proclivity is necessary; in severe cases especially, it will almost invariably be found that the patient inherits the arthritic diathesis. My cases would have shown this more clearly had I paid more attention to this point at the earlier stages of my investigations; but with regard to 19 out of the 29 cases, the result of my inquiries was as follows: In five cases there was inheritance, both of gout and rheumatism; in two of rheumatic gout, in two of rheumatism, and in two of gout, whilst eight patients could give no particulars respecting their families.

I find that I differ greatly from some other members of the profession is my estimate of the severity of gonorrhœal rheumatism. Some appear to look upon it as a comparatively trivial disease, whilst I have met with cases of extreme severity. In the course of my visits to workhouse infirmaries, &c., I found that some of the worst cases of chronic rheumatism were said to date from an attack of gonorrhœa. I found many patients permanently crippled, with joints stiffened, and spine anchylosed, who had fallen into this state after repeated attacks of gonorrhœa; fresh joints having becoming involved after each attack. I am inclined to think that there is a special liability to anchylosis of the spine as a consequence of this form of rheumatism.

Then it should be noted that rheumatism may occur in some patients after very mild attacks of gonorrhœa, and even after what may be called idiopathic gonorrhœa. Patients who are the subjects of the arthritic diathesis are liable to a peculiar form of gonorrhœa, which occurs quite irrespective of sexual connection. I may instance the case of one patient who has had several attacks of this spontaneous gonorrhœa; he inherits gout, and being himself accustomed to live freely, he has added to his inheritance. He is a married man, and there has been no suspicion of any contagion, yet the discharge has been most profuse, and it would be impossible to distinguish the disease from ordinary clap; with each of these attacks his joints have been affected, and his eyes have suffered, so that it has been necessary to perform iridectomy repeatedly. Amongst women we not unfrequently meet with cases of rheumatism closely allied to the gonorrhœal form, but which are due, not to specific, but to simple irritation of the genito-urinary system; and if rheumatism may occur in women from such causes, why should it not occur in men?

Lastly, I may remark that when a large surface of mucous membrane is affected, as when the urethritis spreads to the bladder and to the pelvis of the kidneys, most severe attacks of rheumatism result. One of my patients died and another, a gouty subject, is quite crippled from attacks of this sort.

Although I am aware that the connection of rheumatism with gonorrhœa is generally said to be due to some change in the blood allied to pyæmia, I myself believe strongly in its reflex origin—that it is caused by the influence of the urethral irritation on the nervous system. So long ago as 1872, when I delivered the Hunterian Oration, I chose for my subject the neurotic origin of rheumatism, and stated my belief that gonorrhœal rheumatism was an example of the effects of reflex disturbance of the nervous system. I do not lay claim to any originality in this opinion, which has been advanced by many others as well as by myself, and I would especially call attention to a paper by Dr. Ord, published in the spring of this year, in which he has most ably expounded this view.

Of dysenteric arthritis I cannot say anything of my own personal knowledge, since it has never been noticed in this country. It was first decided by Zimmerman nearly a century ago; he believed it to be due to a metastasis. Since then it has been carefully observed by several Continental physicians. One of the best accounts is that given by M. Huette in a recent volume of the *Archives Générales*. It is apyretic and in all respects closely allied to gonorrhœal rheumatism. It has been especially noticed that it only occurs in persons predisposed to arthritic affections. We have seen, then, that all these causes are much more efficient in persons who are constitutionally predisposed, and the same is true of the less common exciting causes, as loss of blood, and other depressing influences.

Next we may remark that local exposure to the causes of the disease may cause local rheumatism; thus, it may occur in the hand when the hand is constantly exposed to cold, or in the lower extremities when they are exposed to cold and damp, as in farm labourers, and so on.

And, lastly, I must mention a cause of local rheuma-

tism with which surgeons are especially familiar. All here must have met frequently with cases in which rheumatism has been evoked by sprains and other injuries of joints, and must be well aware that rheumatic arthritis thus set up often runs a rapid and destructive course. Thus, in a case of sprain of the hip-joint we may take the greatest possible pains, by careful measurements, &c., to ascertain that there is no fracture of the femur or dislocation of the joint; yet, in spite of treatment, we find that the patient continues lame, and, within a comparatively short period, distinct shortening of the limb becomes evident. I have met with two cases of rheumatic arthritis of the hip-joint in which shortening to the extent of an inch appeared within six months. The importance of these cases is increased by the fact that they are sometimes made the ground of legal proceedings; the absorption of the head of the femur which the shortening indicates may be followed by spontaneous dislocation, and then the presence of the dislocation may be urged as evidence of an error in diagnosis.

I should, then, classify the forms of rheumatism as follows:—

1. General Acute Rheumatism—Rheumatic Fever.
2. General Chronic Rheumatism, or Crippling Rheumatism—the Constitutional Rheumatic Gout of Dr. Adams.
3. Single Joint Rheumatism—Chronic Rheumatic Arthritis, or Osteo-arthritis. This last term I object to as being pathological rather than clinical, and further because it only applies properly to the advanced stages of the disease; there may be no outgrowths of bone, and yet the disease is the same: this form is common enough in old people, but rare in the young.

I should like now to say something more about the influence of the nervous system on arthritic diseases generally. There is no doubt that a low condition of nervous power facilitates the occurrence of these diseases in a severe form. When we speak of persons being in a low tone of health we mean generally that they suffer from clammy hands, sluggish circulation, and general inertia; I mean to include something more than this. Perhaps the best example of disease of the joints occurring in connection with general loss of nerve power is seen in cases of loco-motor ataxy. In some of these cases we get rapid disorganization of the joints, attended by absorption of bone, sometimes by synovial effusion, occasionally by outgrowths of bone, and proceeding at last to spontaneous dislocation; one peculiarity about this form of arthritis is that it is comparatively painless. I have seen a patient in whom both humeri were dislocated and one of the tibiæ was dislocated behind the femur, yet he had suffered little or no pain. Here are some specimens which I found in the museum of the Middlesex Hospital, showing dislocations of the elbow and hip from a patient who was in that hospital some years ago under the care of the late Mr. Campbell De Morgan. The symptoms of loco-motor ataxy were not as well known then as they are now, but the particulars recorded in the clinical history leave little doubt that it was a case of that disease. It is especially mentioned that the patient suffered no pain. I met with a case in the City of London Hospital in which both humeri were dislocated, and there was severe general arthritis, but the ataxic symptoms were not very marked. This patient seemed to me to show the connecting link between chronic rheumatic arthritis and loco-motor ataxy, and I would suggest that this bond of connection lies in the direction of diminished nervous power. The most prominent feature of loco-motor ataxy seems to be rapidly developed senility: there is decay of the sexual function, more or less general anæsthesia, contracted pupils, and loss of power of muscles. It seems to be a sort of premature old age; the changes which occur gradually and naturally in old age occur in loco-motor ataxy as the result of a morbid process. I believe also that there is decay of all parts of the nervous system, though sometimes more marked in one direction than in another, and that the anæsthesia, for instance, is not due solely to changes in certain special strands of the spinal cord, but that the peripheral organs also undergo degenerative changes, that this causes reflex changes in the joints, and this again is aggravated, perhaps by the weakening of some inhibitory influence, by general loss of tone and degenerative changes in the nervous system.

Rheumatism is, then, a neurosis, a form of arthritis due to reflex irritation set up by the action of cold and damp on the cutaneous nerves. Does gout also belong to this class? Dr. Dyce Duckworth has published a paper in which he very ably discusses the theories put forward by Cullen and Laycock to the effect that gout is a neurosis, and he comes to the conclusion that although neurotic influences may have a share in the production of the disease, still it is in great part humeral, and therefore should not be placed in the neurotic class. That this conclusion is correct is, I think, evident from the fact that some people can at any time bring on symptoms of gout by drinking a few classes of a certain kind of wine and then can cure themselves by taking 15 grs. of sodæ bicarb.; the cause of the disease evidently lies in the ingesta. My own opinion is then that *true* gout is purely a humeral disease, and that the undoubted fact that neurotic symptoms do occur in some cases of gout is to be explained by an admixture of rheumatism; the mixed forms of disease being, of course, partly neurotic and partly humeral.

Having already referred to senile arthritis several times I need not say much more about it. I may remark, however, that statistics show that chronic rheumatic arthritis of the hip-joint is very much more common in men than in women. Thus in my own cases there were only 4 women amongst 39 patients, and Dr. Adams does not seem to have met with a single case of this disease in women.

Of these 39 cases 21 inherited a tendency to some form of arthritis; thus 2 had a family history of gout, 9 of rheumatism, and 10 both of gout and rheumatism; whilst in 16 no history of arthritic complaints could be got: this form of rheumatism is, then, less often hereditary than the other forms which I have referred to. And in connection with this fact I may state the following, viz., that in 34 out of the 39 cases the disease of the hip came on when the patient was over 40 years of age.

Original Communications.

SUNSTROKE AS I HAVE SEEN IT IN INDIA

By Surgeon-Major WILLIAM CURRAN,
Army Medical Department.

(*Continued from page 537. last vol.*

Such are some of the cases of this fatal malady that one meets with almost, it may be said, every hot season in India, and it will, I think, be found that, contrary to the dictum of Martin (50) they display a considerable similarity of pathological impression and character. The effects of great heat are, in short, more uniform than those of any other equally fatal disease of my acquaintance, and this, too, is the opinion of almost every writer who has seen cases in point, or studied their morbid peculiarities from the personal standpoint contemplated within. Thus Mr. Marcus Hill, (51) who wrote on the subject in 1855, and whose paper is one of the most practical of its kind that I have perused, "found the undeviating condition of cerebral engorgement, congestion, and the pouring out to a greater or lesser extent of serous fluid" in all the examples of it that came to his own notice; and we may observe that very similar structural changes have been recorded in such cases as occur from time to time in this country. (52) He endorses in the same paper the opinion of an officer who discovered "a subarachnoid fluid effusion of various intensity," in all the examinations he made, and a "hæmorrhagic exudation at the base of the brain, and within the spinal column, was the chief pathological condition

observed on post-mortem" by Mr. Butler (53) at Mean-Meer four years subsequently.

Dwelling on the various theories that have been advanced from time to time as to the cause of this disease, Mr. Hill implies that all the evil depends upon the overpowering heat, and he quotes, with apparent approval, the opinion of a writer who "surmised its essence to be in compression of the brain," the result of the hyperæmia that is produced in that organ "by the influence of great heat." Mr. Butler also found that "when the thermometer ranged beyond 98° in crowded barracks, cases of apoplexy almost invariably occur;" and there is no doubt that "there exists (to return again to our author) an extraordinary analogy between cases of heat-apoplexy and poisoning by carbonic acid gas." So also is there a great resemblance between the effects that are produced by the sun and by the so-called laughing-gas; (54) and it needs only a glance at the treatises of Taylor and Tidy to see that this resemblance or analogy is not peculiar to these substances. But no very reliable or exclusive pathological inference can be deduced from such coincidences, inasmuch as they are common to all conditions of diseased innervation (55) I merely quote them to enable me to dissent again from the view which would make the lungs "the prime organs in the causation of the fatal termination in this disease."

Other observers (56) have been equally emphatic in their testimony as to the lesions they found within the head after death from this disease, and the complications that sometimes follow on recovery from these attacks are more reconcileable with a cerebral, than with a pulmonary, origin or implication. Among these are included such grave complications as mania (57), blindness, meningitis (58), ramollissment, and dementia, and I have often thought that too little allowance is made in police and other courts at home, for those displays of irritability or excitement that are occasionally indulged in by old Indians and others who have been long subject to the sun influences here described. I have also thought that no little of the insanity that obtains in the East is owing in part, at least, to the exasperation that is caused by the heat, while the Malayan paroxysm, or outbreak of "running a muck," may be due to a similar cause enhanced by bang. But the military surgeon rarely sees the more chronic effects of these seizures, as his patients die, or are otherwise disposed of, as by invaliding, transfer to the Hills, &c., and I am therefore unable to endorse in any authentic way the long list of ailments which Martin and others enumerate as consequential on this malady.

I have, however, seen from time to time such minor manifestations as moroseness or irritability of temper, hesitancy or vagueness of speech or manner, drowsiness, somnolence, or actual incapacity for sustained exertion, fidgetiness, and such forgetfulness as amounted to a serious impairment of memory, in persons who have suffered from sunstroke in India, and a brief allusion to the following cases which have occurred, with others of like though less serious import, within the sphere of my own personal cognisance, may serve to explain or illustrate the situation. A recruit of 20, who had been only half a year in India, was suddenly seized with a fit on the parade ground of his corps, and brought thence insensible to hospital. When revived by the douching to which he had been subjected, ice was applied to the head, and his bowels were moved by calomel. He was discharged after a stay of 28 days under treatment, which included blisters to the shaven crown, iodide of potassium and grey powder, but the improvement, such as it was, did not last, and he was brought back in a worse state than before, the second evening after his dismissal. Having subsequently complained of vertigo and indistinctness of vision, the ophthalmoscope was employed, and the retinæ were found to be congested and immoveable. The pupils were dilated and fixed, the orbits were enlarged and puffy, and the injection of the conjunctivæ and intolerance of light previously noticed, persisted. He was found to be all but blind nineteen days afterwards, from, as I considered at the time, paralysis of the optic nerves and other orbital structures. Nor was this condition improved in any way by the frequent epistaxes he suffered from about this time. On the contrary, the globes became more prominent and tender than before; the scalp was also abnormally sensitive to touch or pressure, and all the usual alteratives having failed to afford any relief, mercurials to ptyalism were tried. But all to no purpose, the blindness persisted, and he had to be invalided to England, and discharged from the service.

Encephalitis.—A man, æt. about 30, came under my notice in the Hills for a persistent headache, which he ascribed to the effects of the sun on his head while he was bathing in the open air the previous October. (59) He subsequently fell down in a fit on parade, and when seen by me some months later on, he answered questions slowly but sensibly, but the utterance was hesitating, and the articulation thick, and I came to the conclusion that his memory had sustained irreparable damage. His habits were careless, if not actually dirty. He passed his water frequently, and his fæces occasionally under him at night, and his look was dull, heavy, and inexpressive. The pupils, though regular, were sluggish; the gait was feeble and unsteady; in short, he shuffled rather than walked, and he always complained of a heaviness, which sometimes, indeed, amounted to actual pain, in the vertex. The pulse, soft and very compressible, rarely exceeded 35, and the respiration was equally slow. He continued in this state for several weeks, all the signs of slowly advancing decay becoming meanwhile more marked, and this, too, in spite of all our efforts to the contrary. He cried like a child when pressed for an answer, or responded sullenly in monosyllables, and the use of a catheter, which was passed for the purpose of arresting his dribbling, appeared to cause him no pain. Yet did he eat well—nay, relish his food. The pulse kept steadily, as before, at 34.

On or about the 7th July, however, it was noticed that his habitual stupidity or drowsiness was increasing; his usually pale and passionless expression was becoming more flushed and bibulous, and he "cried" more frequently than before. He also complained more feelingly or forcibly than heretofore of an increased pain in his head. The pupils were slightly dilated, and he either moped aimlessly about the ward, or lay dozing on his cot. The general condition was clearly worse on the 12th of the same month, and he could only be induced with difficulty to mutter some unintelligible answer to a loud or oft-repeated question. He was unable or unwilling to protrude his tongue. The pulse, small and flickering, ran up to 100. He gnashed his teeth frequently, and appeared unable to masticate or swallow solid food. He disliked being interrogated as to his state, or otherwise interfered with, and the left side and arm having become paralysed on the 15th, relaxation of the sphincters soon followed, and he died of exhaustion two days afterwards.

On removing the calvaria ten hours after death, the superficial vessels and sinuses of the dura mater appeared to be loaded with tarry blood, and the brain itself felt softer through its coverings than it really was. It had, however, undergone little or no change in point of consistence, but its membranes were throughout deeply injected, and there were more than two ounces of fluid at its base. About two drachms of a similar fluid were found in the ventricles, and the vessels of the sulci and base were abnormally conspicuous. So also were the bloody points everywhere, but the mass itself only weighed, when divested of all its surroundings, 2 lb. 9½ oz. An absence of serious change was, indeed, its pervading characteristic; but this is a common feature of such examinations, and insanity of even the gravest type is, it is well known, not unfrequently associated with less of it than was present within. The lungs were generally congested, but otherwise healthy, as was also the heart, if I except some evidence of atheroma at its aortic outlet, and the organs presented no feature that calls for record here.

Homicidal Mania.—A young man, of a sullen appearance and sulky manner, who has not been able to attach anyone to himself as a comrade, suddenly developed sym-

ptoms of this character one hot morning during the summer of '78. On this date, and soon after returning from parade, he rushed, without any apparent motive or provocation, towards his rifle, and was found, after seizing it, to be rummaging in his pouch for a cartridge. He uttered, at the same time, fierce threats against the adjutant of his corps, whose life he threatened to take; and he was otherwise so violent and demonstrative as to necessitate his being placed under restraint, and sent for observation to the hospital. Here he required as many as six men to control him during a most violent paroxysm of maniacal rage and excitement, during which he again launched out into threats against his superior, and his convulsions were simply terrible. He also shouted almost continuously for "cheroots and porridge;" he had an almost insatiable thirst, but little or no appetite, and chloral and bromide of potassium appeared to be thrown away upon him at this time. He recovered, however, subsequently so far under the use of purgatives, quietude, and cold to the head, as to be able to converse freely with his attendants, and he was quite quiet and rational about six weeks after his first outbreak.

He has, it appears, once suffered from sunstroke, during which he was, he alleges, insensible for three days; but we have no other record of this than his own statement, and there is, undoubtedly, an epileptic element in his case. He also persists in ascribing his present illness to that attack, and adds that he has ever since been subject to headache, and fits of moroseness or irritability of temper. This may be so or not, as far as I can now ascertain, and I merely give this narrative as an illustration of the assumption—for it is, at least, nothing more—here indulged in. I never before saw a precisely similar case; neither is it, in point of suddenness or severity, incompatible with an attack of acute mania, pure and simple; but then the recovery was more rapid and complete in the one instance than it usually is in the other, and I and others who saw him at the time, fully believed that his illness was in this instance, mainly if not entirely, due to the sun. So believing, I retain it among my complications of sunstroke, and I have already propounded a very similar impression as to the character or cause of the irritability, or rather eccentricity, that so often characterises the conduct of persons who have resided many years in the tropics.

As to the relationship, or rather identity, that is said to exist between heat-apoplexy and congestive, remittent, or other form of tropical fever, as well as to the opinion that it is only an enhancement, or rather an aggravated expression of ordinary ardent fever, (60) not much need be said, and the view which would imply an identity of nature between the two on account of their frequent association or sequential relationship, seems to me to be as unphilosophical as that which would establish the kinship of diarrhœa and cholera on a similar basis. That one frequently follows the other, if indeed, the graver complication is not always preceded by the lesser one, cannot be denied; but this only proves a community of cause and constitution, and the question scarcely admits of a solution on clinical grounds. Neither will, I feel assured, pathological anatomy be able to settle it, while its discussion from any other point of view would be irrelevant here. Suffice it to say that sunstroke is, in my judgment, a disease *sui generis*, which has its own special life-history and symptoms, and which exhibits within and without the body an altitude and a persistency of heat, such as finds no parallel in any, even the worst forms of ardent or remittent fever. Whether the blood is affected, at the same time, to an equal or greater extent, I am unable to say; but I think it is, and I feel assured that were the temperatures of the three great corporal cavities carefully compared in the dead-house, they would be found to decrease in a descending, though it may be an infinitesimal, ratio from above downwards. Moreover, the heat that sometimes admits of a cure in the former, is almost invariably fatal in the latter; and I have seen or heard of recoveries in sunstroke when the thermometer registered 110°. Such a phenomenon is, I believe, unknown in either of the others; and feeling that in thus taking up such collateral issues at all, I am far exceeding the limits of an ordinary professional paper, I must now resume the thread of my discourse, and hasten, or rather rush at once, to a close.

(To be continued.)

---

(50) See his "Influence of Tropical Climates," p. 399, whereat he says that "the post-mortem appearances in this disease vary remarkably; so much so, indeed, as to show that out of several casualties the causes of death are different, the inconstant nature of the morbid results depending on the constitution, condition of the blood, the duration and intensity of the solar exposure, the amount of fatigue, the habits of life, and the duration of the disease." [Longe mea discrepat istis et vox et ratio.]

(51) *Op cit.*, pp. 231 and 240.

(52) The following account of the appearances that were found, in a London Hospital, in the body of a man, æt. 60, who died from this disease in July, 1868, is taken from the *Lancet* of July 25 of that year, and the exosmotic conditions italicised below were, I think, necrotic:—"The body was much decomposed. The brain was intensely congested, and of a pinkish hue throughout; the puncta vasculosa were greatly increased in number, and *around the larger ones there was a distinct halo of discolouration, due to the soaking of the blood through the walls of the vessels;* the ventricles contained a quantity of deeply-tinged bloody fluid; the substance was of firm consistence, and the central parts were not broken down. The lungs were very much congested, especially the lower parts, where they had the appearance of pulmonary apoplexy, except that it was not in circumscribed patches, but uniformly diffused throughout the whole structure. The heart was uncontracted and empty; the structure was fatty and rotten; the valves blood-stained; the aorta was very atheromatous."

(53) "Indian Annals," as above, No. xii, of 1859, pp. 412-13.

(54) "On incising the scalp (in the body of a surgeon who died under the effects of nitrous oxide gas, and whose case is described in the *Lancet* of April 14th, 1877) a quantity of dark fluid blood was found between it and the periosteum, while on removing the calvaria the dura mater was found very adherent; the membranes were found distended with serous fluid, and the veins were intensely congested. The ventricles were also filled with the same fluid; the brain substance itself was firm and healthy. . . . . and the lungs were very dark-coloured and intensely congested." Very similar conditions were found in India in the bodies of persons who died there from the "inhalation of poisonous gases generated in a grain kiln."—*Indian Medical Gazette* for November, 1874, p. 295.

(55) The brain is "sometimes," according to Dickenson, ("Diseases of the Kidney," p. 32), "obviously congested in whole or in part," in death from diabetes. Sugar was found in the urine of two, at least, of the cases recorded in my (suppressed) table; and I found traces of albumen in some of the others myself.

(56) See especially the "Indian Annals," No. xii., p. 527.

(57) There is a curious entry in the "Autobiography of Miss Knight," vol. i., p. 61, to the effect that "during the great heats of July, 1781, many people went mad. Amongst others a bricklayer, in his madness, killed a priest. He subsequently at one stroke killed a very beautiful woman, broke the arm of another woman wounded another priest, and in fact altogether killed or wounded seven persons." See also Silk Buckingham's "Autobiography," as above, vol. ii., p. 16, in the same direction.

(58) It may be that this was the diabolical object or purpose with which the robber Pindaries, as Lutfullah testifies, exposed their prisoners for days together in the sun, with heavy weights on their heads. When they wanted a speedier issue they enclosed their victims' faces in a bag of heated ashes, *pour decourager les autres;* and Mrs. Ida Pfeffer testifies, if I misremember not, to the existence of a very similar punishment in her day in Madagascar. The Supplementary Despatches of F. M. Arthur Duke of Wellington give an instance (vol. iii., p. 18) in which an officer was tried by a court-martial for making "certain natives stand in the sun at Seedsheeghaur with stones on their heads;" and Anderson supplies (*op. cit.*, p. 136) an equally interesting account of some Minorite friars who were done to death in this way by order of the Kazi of Tanna, for "plainly avowing that Mahomed was the son of perdition." Further particulars in point may be found in Dr. John Fryer's "Account of India" (London, Trübner), pp. 296-7, and also in James Mill's well-known "History of India," vol. i., p. 351.

(59) Old Burton describes in his usual vein, and on the authority of Amatus Lusitanus, "a young maid of thirteen that would wash her hair in the heat of the day (in July), and so let it dry in the sun to make it yellow; but by that means, tarrying too long in the heat, she inflamed her head, and made herself mad." An old French poet represents one of his heroes as promenading in the sun to dry his wig:

"Hector se promene au soleil
Pour faire sécher sa perruque."

(60) Dr. A. Smith (*op. cit.*, p. 195) is the latest advocate of

this view that I am acquainted with, and he appeared to regard it as a discovery. But in this, as in other instances, the proverbial little learning has sustained its old repute for shallowness, and had this gentleman dipped a little deeper into the literature of the subject, he would have found that "Vixere fortes ante Agamemnona multi."

DESCRIPTION OF AN INDIA-RUBBER INHALER FOR ETHER ANÆSTHESIA.

By B. WILLS RICHARDSON, F.R.C.S.,
Senior Examiner in Surgery, Royal College of Surgeons, Ireland; Surgeon to the Adelaide Hospital, Dublin.

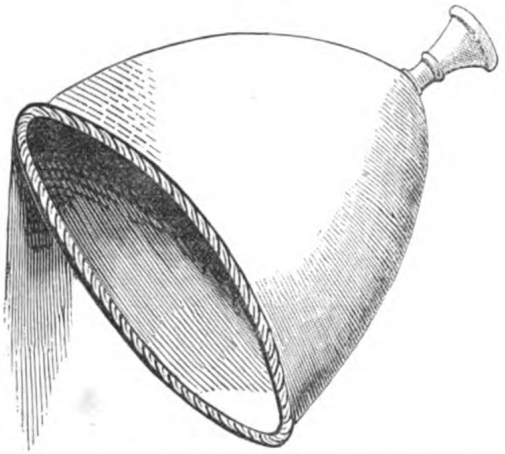
In the *Dublin Journal of Medical Science* for March, 1873, I published a description of a metallic ether inhaler of simple construction and portability. But subsequently finding it rather expensive for general use, I devised an inhaler of india-rubber, which works efficiently, economises ether, and may be purchased for a few shillings.

This inhaler the Messrs. Fannin (*a*) had constructed for me many months ago, and since then, I may say, it has been used with almost every operation case in the Adelaide Hospital.

When first made, the inhaler had no funnel. This I have recently added to avoid the necessity for raising the inhaler from the face to replenish the ether. By this addition anæsthesia may be either hastened or maintained with facility and ether still further economised.

The inhaler is conoid in shape and formed of vulcanised rubber (Fig. 1), and may be of different dimensions. The

FIG. 1.



measurements of the one I use are as follow: Diameter at mouth, 9 inches; vertical axial depth, exclusive of the funnel, 7 inches; depth of funnel, 2¼ inches; the diameter of its mouth being about 1 inch.

Near the top of the inside of the inhaler two crossed bands of rubber are cemented as seen at B, Fig. 2. These are to retain a piece of sponge in position as seen in the drawing. The sponge receives the ether through the funnel, the walls of which should be of some substance, but yet sufficiently thin to allow of its easy closure by finger pressure, should it be desirable to prevent air passing towards the sponge.

I myself generally close the funnel after each ether renewal, until near the conclusion of the inhalation, when I allow the air to enter.

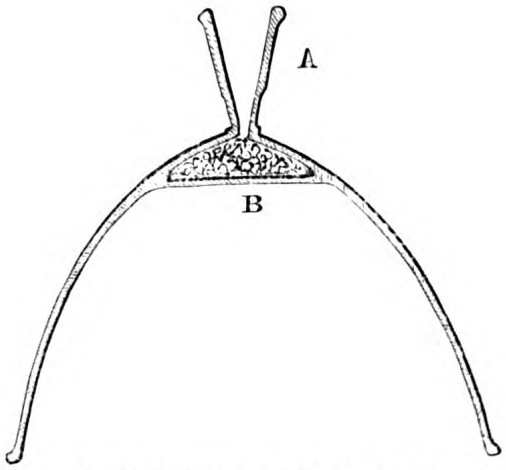
I need scarcely remark that air will enter the inhaler at its base; this I limit by taking up a fold of the rubber with the fingers.

For these antiseptic days a rubber inhaler possesses a great advantage in the facility with which it can be cleansed, which should be done after each inhalation.

In the paper in the *Dublin Journal* to which I have alluded I wrote as follows, in speaking upon the relative safety of chloroform and ether as anæsthetics:—

"I confess that I am myself in favour of a mixture of equal parts of chloroform and spirit of wine for producing anæsthesia, and therefore it is the comparative safety of this fluid I purpose testing against the ether."

FIG. 2.



SECTIONAL VIEW OF THE INHALER.

A. Funnel.
B. One of the bands, above which the sponge is represented.

Since those lines were written I have altogether relinquished the use of chloroform from the serious medico-legal position into which its fatality has plunged it.

To me it is a matter of surprise, considering the numerous deaths attributable to chloroform, that its use is not more limited.

"Although deaths," as I wrote also in the paper referred to, "it must be conceded have resulted from the inhalation of ether, I will, notwithstanding, reproduce here the following observations of Snow regarding the safety of ether, as an inducement for the trial of ether by those who are not disposed to do so in consequence of their having had good luck in the use of chloroform."

"I believe," he has recorded, "that ether is altogether incapable of causing the sudden death, by paralysis of the heart, which has caused the accidents which have happened during the administration of chloroform. I have not been able to kill an animal in that manner with ether, even when I have made it boil, and administered it quite pure."....."I hold it, therefore, to be almost impossible that a death from this agent can occur in the hands of a medical man who is applying it with ordinary intelligence and attention."

In conclusion I should state that the face and about the front half of the head should be covered by the inhaler, which, as I have already observed, may be folded to lessen the amount of air entering the cone.

Clinical Records.

ST. PETER'S HOSPITAL, LONDON.

A Case of Recurrent Calculus in a Man who had been twice cut for Stone—Lithotrity—Good Result.

By W. F. TEEVAN, B.A., F.R.C.S.,
Surgeon to the West London Hospital, Surgeon to St. Peter's Hospital, late Lecturer on Anatomy at the Westminster Hospital.

THERE is no doubt a general belief in the profession that recurrence of stone is very common after lithotrity, but rare after lithotomy. My own experience does not bear out this view. It is perfectly true that we hear and see more of recur-

rence after lithotrity for the simple reason that more patients are left alive after lithotrity than after lithotomy, "*mortui non mordent.*" Not only is recurrence after lithotomy more common than is thought, but it takes place again and again in the same subject, as in the case I am about to relate.

On April 7, 1873, David W., a miller, æt. 49, was admitted under my care at St. Peter's Hospital suffering from cystitis and stone in the bladder. It appeared that fifteen years previously the patient had had two calculi extracted by Mr. Cadge, of Norwich, by the lateral operation. He made a good recovery, resumed work, and at a later date settled in London. For about nine years he remained perfectly well, when he began to suffer from a recurrence of his old symptoms. He went to one of the chief hospitals in London, and was admitted as an in-patient. After remaining in the institution for six weeks he found himself no better, and left of his own accord. He then went to Norwich to again consult Mr. Cadge, who examined him, found a stone, and removed it by the lateral operation, performing it on the same side as before. The patient returned to town quite well, resumed work, and remained in good health and free from any local annoyance for about six years. He then began to ail again, and to be troubled in his old quarter. For one year previously to coming under my care he had to micturate every ten minutes, and suffered much pain in the act. At times he experienced great pain across the loins, and his urine had, for months, contained much blood, mucus and pus. When admitted he was in a very cachectic condition. He had lost flesh, and his clothes hung on him. Day and night he was tormented by frequent calls to micturate. His urine was a mass of bloody muco-pus, smelling offensively. He suffered much from tenesmus, and his penis was usually semi-erect from pain and irritation. He was unable to ride in an omnibus on account of the suffering he experienced from the jolting. I examined him, and found a small stone about the size of a hazel-nut. On reviewing the history of the case it appeared that the patient, when robust and in good health, had had lithic acid calculi last; I felt that I had now to deal with a case of cystitis, and that the stone was altogether a secondary matter of local formation. I knew that there would be no trouble in crushing and removing the calculus, but I considered the cystitis would be difficult to cure. As the patient was so broken in health, I fed him up well for a fortnight, and gave him medicines to allay the local irritation. In three crushings I completely removed the stone, which was phosphatic, and the patient experienced much relief. The cystitis, however, did not disappear, and a long course of injections of nitrate of silver alone cured the complaint, so that he did not leave the hospital till July 12. On August 8, 1874, one year after he had left, he paid me a visit. He had grown stout again, and his complexion was florid. His urine was quite clear, acid, and its sp. gr. 1020. He simply came to report himself in accordance with my wish, and had nothing to complain of. He had been at work uninterruptedly since he left the hospital. It is very evident that the calculi were true recurrent ones, for many years of perfect health and complete immunity from all local annoyance intervened between the recurrences, proving that the stones were fresh formations.

It is worthy of remark that when the patient was in good health he had uric acid calculi, but when through night work he fell into bad health, cystitis set in, caused probably by tubercular follicular ulceration of the bladder. A phosphatic stone formed as the result of the cystitis; the urine becoming entangled in the mucus, and decomposing. By good feeding and injections the patient was cured of his cystitis. There was no history of syphilis in the case. It may be laid down as a rule, that no patient, unless a boy, need ever be subjected twice to lithotomy, for the operation can only become necessary through the patient's neglect or oversight on the part of the surgeon. Every stone must have a beginning, and if the earlier symptoms be attended to, the calculus can be easily and safely disposed of by lithotrity. Hence, it is well to inform every patient who has been cut that a recurrence of the complaint is possible but not probable, and indicate to him the symptoms of such recurrence. If, therefore, a patient applied for advice whenever any of his old symptoms re-appeared, a second lithotomy ought to be an impossibility, and we may assure him that the worst which could possibly happen to him would be that he would have to put up with a momentary introduction of the lithotrite to destroy a stone in its infancy. In this way lithotrity is an inestimable boon in store for those who have been cut, for it abolishes the fear of any necessity for a second cutting operation, and if the lithotrite had done nothing more it had deserved well of mankind. However, so long as the human race is constituted as it now is, there will always be patients who will neglect themselves, and there will always be surgeons who will overlook the presence of a stone. The idea of the possible extermination of calculus may be well relegated to Utopia. All we can hope for is, that the percentage of stone cases condemned to be cut will be materially diminished, and increasingly so every year.

LA PITIE HOSPITAL, PARIS.

Case of Tuberculosis—Pott's Curvature—Addison's Disease from Tuberculosis of Suprarenal Capsules.

Under the care of Professor PETER.

J. B., æt. 42, was admitted into La Pitié Hospital, under the care of Professor Peter, Sept. 25, 1879. He had had good health until a year ago. About that time he felt dull pains in the dorsal region, for which he consulted various physicians. They treated it as rheumatism, but no remedy gave any relief, and about two months ago a new phenomenon manifested itself which accounted for the failure of the treatment. His vertebral column became depressed, and the curvature which was found on his admission had increased very rapidly. About the same time the patient noticed that his skin was changing colour; it became brown, principally on the hands, where the change of colour was the more marked, because some spots remained absolutely white. Very soon the hair, eyebrows, and the beard became manifestly blackened, to the great astonishment of the patient, as they had previously been of a pale chestnut colour. The patient soon became very weak, lost his appetite, and suffered dull—sometimes acute—pain in the right flank and lumbar region. There was no vomiting, but frequent diarrhœa. For some weeks he had had a dry, hard cough without expectoration.

On admission his face was expressive of fatigue and dejection. He suffered much pain in the loins, and could scarcely remain sitting on his bed any time. The face, trunk, and limbs were of a remarkable dirty-brown colour, very similar to that of a somewhat pale mulatto. The colour was almost uniform over the whole skin, except in the following regions: on the scrotum, where there were two large white patches (vitiligo); on the hands and feet, where the digits at their extremity, both on the palmar and plantar surfaces, showed irregular white spots. Two white cicatrices, the traces of cautery applied six months previously, existed on the dorsal region. There were also some pigmented patches on the inner surface of the lips and cheeks. The spinal curvature occupied the tenth, eleventh, and twelth dorsal vertebræ. In the triangle of Petit on the left side was a soft, fluctuating tumour, the size of a small mandarin orange. This was diagnosed as a migratory cold abscess. The lungs showed signs of slight induration of both apices, especially on the right side under the clavicle. Urine normal. The patient remained thus for ten days. On the 8th of October he complained of severe pain in the right flank, and a flying blister was applied to the spot. Feebleness increased daily.

Oct. 15.—The pigmentation of the skin has increased, and the patient is now black. The cough has increased, and sharp fever has come on. In the right apex is a bronchial souffle, with some fine moist subcrepitant râles.

Oct. 25.—The patient died in a state of great weakness. The fever has continued for the last ten days, oscillating between 39° and 40°.

Autopsy.—Both supra-renal capsules considerably enlarged in size; still roughly maintaining their shape, they are knobbed, very hard, yellowish, and occupied, as is easily seen on section, by a number of tubercular masses, mostly caseous. In the right capsule some of the tubercular masses had become calcareous. Kidneys slightly enlarged, very congested. Some young tubercular granules scattered through the cortical layer of both kidneys. The pre-lumbar lymphatic ganglia much enlarged, red; some appear pigmented with blackish patches; some of the mediastinal ganglia similarly swollen and slightly pigmented. Two large cold abscesses situated at the level of the cold region of the spine. One seemed attached to the body of the twelfth vertebra, and caused considerable projection in the region of Petit; the other was on the right side of the dorsal column, extending from the eighth to the lower part

of the body of the twelfth vertebra, and on opening it the bodies of these four vertebræ were found denuded.

The whole of the bodies of the eleventh and twelfth are carious, and the articulation is destroyed. The caries is manifestly tubercular, whitish caseous masses being found in the thickness of both vertebræ. Spleen large, and infiltrated with some tubercular granules. Liver, small, fatty, with slight peri-hepatitis of the right lobe. No other trace of tubercle in the peritoneum. In the lungs, tubercular infiltration, of comparatively recent date. At the highest part of the right apex some yellowish caseous masses, not calcified, evidently old. Considerable congestion at both bases, and in the lowest part of the lungs some grey scattered granules. Old pleural adhesions, extending through the whole of the right lung, less numerous in the left. The mucous membranes not pigmented; with the exception of the black patches mentioned in the buccal cavity, their colour is normal.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, JULY 7, 1880.

THE ARMY MEDICAL REPORT.

THE Blue Book for 1878, which has just been published, contains much that is of very great value in connection with the medical history of the army; yet we cannot help thinking it a pity that in the statistics of diseases given, the individuality of regiments is, to a great extent, ignored; thus, one of the very points in which such documents would be of greatest use, for purposes of comparison, is left unfulfilled by them. The death-rate per 1,000 troops in the United Kingdom during the year 1878 was 6·53 per 1,000 strength, discharged as invalids 33·60; thus making a total loss by these two causes equal to 40·13 per 1,000 men. The death-rate of the male population of England and Wales from under 20 to 35 is 8·92; but this ratio includes all classes, invalids and others, whereas in the army, consisting of picked lives, the mortality represented as taking place in it is really that of a selected class, and chiefly by first attacks of illness, inasmuch that many who survive from such attacks pass into the category of invalids. Of course there are many men who break down in health after enlistment from causes altogether unconnected with the army. We find at page 26 an interesting table, showing the disabilities on account of which a proportion of recruits were rejected; and a corresponding table showing the causes of invaliding would furnish an important means for comparing these two points in their relation to public health. At Gibraltar the loss per 1,000 strength was, by death, 6·59; by invaliding, 50·62; total, 57·21. It is right to observe that these figures refer to the soldiers who were sent home as invalids; the ratio to strength of men so designated, actually discharged this year, appears to have been 24·67; but information does not appear as to what became of the balance, namely, 25·95. We presume that a portion of them rejoined depôts, but that more than a mere fraction of these became efficient soldiers we hesitate to believe. At Malta the rate of death of British troops was 12·26, of invaliding 48·70, total non-efficiency by disease, 60·96. At Cyprus the statistics worked out as for a year, show a ratio of death equal to 40·27 per 1,000 strength, of invaliding, 157·01, making a total of non-efficiency by disease equal to 191·28; surely an eloquent commentary upon those charming accounts of this new-found Elysium which it suited the purpose of some advocates to give. Turning from this to Canada, we find that the ratio of death in the latter command was 5·80, of invaliding 15·65, equal to a non-efficiency, 21·45; this against 40·13 in the United Kingdom, or an advantage as regards soldiership and efficiency equal to 18·68 per 1,000 in favour of Canada. Let us by all means go to Canada! In Bermuda 5·95 by death, 16·86 by invaliding, showing a remarkable measure of health such as this group of islands usually enjoys in the intervals between outbreaks of yellow fever. In the West Indies 13·40 by death, 6·26 by invaliding, or total of 19·66; a striking difference in the relative proportions of these causes of non-efficiency when compared with such as we have found in the other commands enumerated. There appears to have been only twelve non-commissioned officers and men on the West Coast of Africa, and it is satisfactory to learn that among them no death occurred. The statistics of the troops at St. Helena, and at the Cape of Good Hope, are, unfortunately, given together; thus it becomes impracticable to separate the effects upon health and life of these two climates, and of the conditions incidental to each place. According to a table given, the rate of mortality throughout this combined command was 19·72; of invaliding, 26·11; making a total loss equal to 45·83. In Mauritius the ratio of loss was by death 31·25; invaliding, 40·87; equal to a total of 72·12 per 1,000 effectives. In Ceylon the ratio of mortality was 15·76; invaliding, 28·57; total, 44·33. In Hong Kong the ratio of deaths was 13·03; of

invaliding, 146·57; giving a total non-effective equal to 159·60; a proportion that is something altogether beyond that shown by any other station. With regard to India, the statistics are given of each of the three Presidencies separately. According to them, the ratio of non-efficiency was as follows, namely:—

	Deaths	Invalided	Total.
Bengal . .	22·18	42·75	64·93
Madras . .	23·25	45·77	69·02
Bombay . .	21·65	58·49	80·14

According to these figures the circumstance is rendered sufficiently clear that mortality has, among our troops in India, been very much reduced as compared with previous periods; the rate of invaliding, however, has increased to a very large extent; and this, notwithstanding the improved sanitation of late years, including the more general plan of sending men to hill stations. These results are, no doubt, due to the system of short service, necessitating, as it does, a large yearly influx into India of young men; such of them as die succumb to the first serious illness to which they are subjected, while those who escape such illness with their lives are returned as invalids to England by those magnificent troop-ships that yearly carry out the "reliefs" between this country and India.

The Report contains various particulars on the subject of age as affecting mortality, and in these respects the statistics of 1878 are compared with the ratios of the period from 1868 to 1877. As regards temperate climates, there is no very great difference between the two sets of figures, but in some tropical stations they are very dissimilar. With regard to India the ratio of deaths according to age give, under 20 years, 6·15 as against 8·17 from 1868 to 1877; 20 to 25 years, 19·82 as against 14·89; 25 to 30, 20·93 as against 17·46; 30 to 35, 22·71 as against 25·34; 35 to 40, 23·88 as against 31·55; 40 and upwards, 63·46 as against 53·24.

DUBLIN SANITATION.

At length the Report of the Royal Sanitary Commission has seen the light, and the public has before it a solemn declaration of fact and of conclusion which is of priceless value as putting beyond dispute the causes of the monstrous unhealthiness of "the second city in the empire." Reading the chorus of concurrent evidence taken by the Commissioners side by side with the verdict arrived at by those gentlemen, and in the additional light of the Registrar-General's weekly death returns, no possibility of doubt remains that Dublin, though truly called "second" in size and in population amongst the cities of the empire, is proudly first in the pre-eminence of dirt, neglect, and uncivilisation, and unquestionably last in decency and in the executive capacity of its sanitary administrators. A more complete laying naked of festering corporate rottenness has never been the duty of a commission of inquiry, and, though every line of the Commissioners' summing up of the case bears evidence of a desire to say as little that is unpleasant as may be possible, an exposure more disgraceful to the sanitary management of any city has never occupied a place within the pages of a Parliamentary Blue Book. We cannot be expected to appreciate the feelings with which a Public Health Committee which has displayed such a supreme capacity for "how not to do it" will read (if they think it worth while to read) the "round unvarnished tale" of the abominations of the Dublin tenement houses, nor can we be supposed to judge of the sensations of officers of health who have been broken-in to an indifference on such subjects, when they are told of the atrocities of insanitation over which they have presided for many years; but we should fancy that even the stoical Public Health Committee and its nonchalant officers must feel an inward twinge of conscience and show an outward blush of shame when they recollect that for all these years their energies and their ingenuity were devoted to the effort to persuade the clamouring citizens that the city was as nice, clean, and wholesome as other cities, and that the excessive death-rate was all due to mistakes in registration, or the weather, or the "mud valley" of the Liffey, or the perversity of the poor, or some other cause which was a visitation of Providence altogether outside their control. In every page of this Report they are branded by the facts sworn to as having not only grossly neglected their sanitary duty, but deliberately and persistently uttered false excuses for the continuance of that neglect. The solid legion of sworn facts and the inevitable sequence of truthful deductions from those facts which the Report contains, sweeps away for ever the remaining shred of confidence in the public health administration of Dublin under the Corporation, and, at the same moment, takes from the citizens the only excuse they had for their lethargic indifference to the mortality in their midst. Henceforth, if it pleases them to live in the focus of a death-rate such as that of Calcutta or Cairo, they do so, at least, in full official knowledge of the facts, and they will deserve no sympathy when the City is decimated, as it has been by dirt epidemics.

It is, we regret to say, impossible for us to print even a tithe of the contents of the Report, or to dwell upon it at half the length which its importance deserves. The demand on our space obliges us to confine ourselves to an abstract of the conclusions at which the Commissioners arrive, and which state briefly their verdict as to the cause and result of Dublin mortality. They report:—

"That new sewers are required, but the entire system of sewers and drains should be more fully ventilated.

"That house-drains are proved to be very defective, and that the yards, courts, and back streets are for the most part defectively drained, and very dirty in consequence.

"That the privy accommodation is generally defective throughout the poorer quarters of the city, and that it is in the tenement-houses practically absent, and that as a consequence the inhabitants suffer both in health and in morals. The tenement-houses of Dublin, according to the medical evidence voluminously tendered at our inquiry and embodied in this our report, appear to be a primary source, and the cause of the excessively high death-rate.

"That they are not properly scavenged, ventilated, and regulated.

"That they are dilapidated, dirty, ill-ventilated, and much over-crowded, and that disease and craving for drink, and consequent drunkenness and extreme poverty, are thereby fostered; and until the condition of these houses has been improved the general health of the city will continue to be injuriously affected.

"That most of the courts and yards in connection with the tenement-houses are unformed and unpaved, and that as a consequence there is an accumulation of offensive dirt, general discomfort, loss of health, and loss of power to earn wages.

"That many of the streets are formed of defective materials.

"That public scavenging is inadequately performed. There is no municipal system of private scavenging, and as a consequence the streets are dirty, the courts and yards are at a l

times filthy, and in our opinion the cleanest and cheapest mode of removing excreta will be by water, through water-closets, drains, and sewers to a common outlet. Houses must be drained, streets must be sewered so as to remove waste water, and, if these drains and sewers are well and truly constructed, to transmit the entire volume of excreta of the houses and city.

"That both public and private manure depôts are at present in improper places in the city.

"That some of them are situated in courts and yards surrounded by dwelling-houses, and consequently injurious to the public health.

"That slaughter-houses, cowsheds, and dairies are in improper places within the municipal area, and that some of them possess no adequate appliances for drainage, cleanliness, and ventilation.

"That there is no adequate provision for baths and wash-houses specially planned and adapted for the benefit of the working-classes, and that the inhabitants of the tenement-houses, having no washing and drying accommodation, cannot properly cleanse themselves or their garments.

"That there is an abundant supply of soft water for all public, private, and domestic purposes brought into the city from the Vartry Works, but that it is not made so fully available for the use of the inhabitants of the tenements as is desirable.

"That a more efficient filtration of the water is required.

"That Section 108 in the Public Health Act is not worked and duly enforced in Dublin with a view to the prevention of nuisances arising from smoke contamination of the atmosphere.

"That, considering the extensive sanitary improvements necessary in Dublin, we are of opinion that the superintending medical officer of health of the city should devote his whole time to the duties of his office.

"That the river Liffey is polluted by the sewers of Dublin so as to be offensive.

"That, though appearing not directly injurious to the health of the inhabitants, it is, in our opinion, prejudicial to the interests of the city and port of Dublin.

"That, on the evidence placed before us, we cannot hold the Liffey accountable for the high rate of mortality which has prevailed and continues to prevail within the district which it traverses; and that while we regard these improvements of the houses and drainage of Dublin and of the tenement-houses, better scavenging and filth removal, and improved road formation, as matters urgently necessary for the improvement of the public health, we are also of opinion that the river Liffey and the port and harbour of Dublin ought to be free from the pollution."

When we consider the extreme pressure exercised by the Chief Secretary, the Irish Local Government Board, and the Dublin Corporation, to prevent the Commissioners either inquiring into the true causes of the death-rate or expressing their views thereupon, we must feel great satisfaction with the Report before us, and we are bound to return to the Commissioners the warmest thanks of the citizens for the labour they have performed, and the honesty of their declarations. We were naturally impatient to see the result of their inquiry, knowing that no step towards amendment could be initiated until the Report had been completed and digested, and we confess to have been seriously apprehensive that the pressure exercised by Mr. James Lowther, by the Vice-President of the Local Government Board, and by the Corporation, would have been too much for the independence of the Commissioners. We are gratified to have to admit that we did them an injustice, and we say, without hesitation, that the pronouncement to which they have given utterance is creditable to them, and of extreme value to the citizens. But for the perseverance of the Dublin Sanitary Association, to whom Dublin people owe more than they seem to feel, and the courage of the Commissioners, Dublin might remain for many a weary year the victim of every mood and tense of sanitary mal-administration. Let us hope that a continuance of the *status quo* maintained by the Lord Mayor and Corporation of Dublin is no longer possible.

GUY'S HOSPITAL.

THE condition of affairs at Guy's Hospital presents no favourable change, unless this can be said to have occurred in connection with the appointment of an impartial committee for the purpose of *investigating* the events and their causes to which the deplorable state of Guy's is to be attributed. This committee consists of the following gentlemen: Sir Thomas Acland, Sir Trevor Lawrence, Messrs. R. Harvey, Shaw Stewart, C. Barclay, and Samuel Hoare, and it has already commenced its deliberations. Since the committee is apparently endowed with no power to do more than sum up the facts already fully known to the world, and, possibly, comment on them, it is difficult to understand what good effect is likely to result from its sittings. There is not, that we are aware of, any doubt entertained in unprejudiced minds that the "innovations" complained of are fully deserving all the condemnation they have received from the professional staff of the hospital. No more is it to be denied that there is but one way open to restore the *prestige* of the Borough charity to anything approaching the heights from which it has been deposed. The *onus probandi*, if it can be said to rest anywhere when opinion is almost universal, lies certainly with the two officials who persist in maintaining an attitude of determined opposition to the wishes of all their *confrères* in the administration of the hospital. Under the circumstances, therefore, a committee of reference is that alone for which any *raison d'être* can be shown; but in the announcement made public concerning its appointment there is nothing to prove that it is anything more than a mere court of inquiry without judicial power of any sort or kind. It may well be asked with regard to it, *cui bono?*

Complaints, and rumours of complaints without end, emanate from the unfortunate hospital, so much so that there is no possibility of believing that there is any excuse for the continuance of a *régime* which, according to the newest utterances, is chargeable with a mortality unprecedented in the annals of Guy's. It is well to consider whether the time has not arrived for invoking the aid of external authority to effect the restoration of order, since the well-being of some six hundred patients is said to be jeopardised by the questionable nursing arrangements under which they are placed. Not a few who have carefully watched the progress of the quarrel, and the disastrous consequences ensuing from it, are disposed to think that earlier and decisive action should have been taken by the medical staff, action which would have at once and effectually settled the matter in dispute. By the resignation of these officers, attention would have been drawn to the subject from all sides, and the most searching inquiries would have been made, ere the public rested satisfied with the ultimate adjustments. It is idle to suppose that the threat stated to have been held out, that wholesale resignation would be followed by the appointment of an entire new staff subservient to the wishes of the treasurer and his nominee to the matron's

post would have been carried out. Some 60,000 to 70,000 patients annually apply for relief at Guy's Hospital, many of the cases being of the most critical nature, demanding for their successful treatment the skill and experience of tried and responsible physicians and surgeons. That the treasurer would have been allowed to gratify his inclinations by submitting this vast amount of suffering and disease to the potential elements possibly residing in untried, inexperienced practitioners, such as could alone be expected to usurp the places of the retiring staff, is a monstrous absurdity. There is, in the ranks of the medical profession, no person of eminence who would not reckon it as a deepest insult were he solicited to tender his services under such circumstances. Unquestionably there may be a sufficient minority who would exhibit little hesitation in availing themselves of any opportunity to enter on duty as honorary attendants at Guy's. Time was when this was open to doubt, but later events have proved the contrary. Nevertheless, the injustice that such a proceeding would be to the sick poor, who regard Guy's Hospital as the place where their ills will receive the most skilled treatment possible, would be too glaring, too apparent to the least reflecting of the general public, for universal indignation not to have straightway arisen against the author of the enormity. Doubtless it would be an unmitigated hardship also to the staff to be compelled to follow such an untoward course, but the assurance of popular sympathy, and the practical support of their professional brethren, ought to suffice to render the step an easy one. The interests of a great charity are not to be made the plaything of a single individual. When it becomes apparent that, by unfortuitous circumstances, the power to wreck the *prestige* of, and minimise the benefits conferred by, a world-known institution rests in one person's hands, and he shows a determination to use his power to the utmost, there arises a need for instant and extreme measures. Until this time it must be admitted these have not been resorted to, and even now there is the appearance of dallying with danger rather than resolutely stamping it out of existence. There are, fortunately, higher authorities than that even of the court of governors to direct the affairs of Guy's Hospital. Only in desperate need, however, ought they to be invoked. But the need can be said to have arisen, and the voice of public opinion may be trusted to speak with no uncertain sound when once it recognises the real import of the issues at stake. We have from the outset deprecated the necessity for publicity in the matter, but when it becomes a question of the safety and lives of considerably more than fifty thousand people, there is occasion for something more than a class consideration of the details of the case.

The undignified performances of the senior resident medical officers at Guy's Hospital in connection with the students' demonstration against the treasurer, has not served to establish confidence in the attitude of firmness to be expected from the staff as a whole. It would be unfair, however, to attach much importance to the acts and utterances of two senior students simply. A smile may be provoked by their readiness to acquiesce in the demand made to them to reassume the humble position out of which they for a moment emancipated themselves, but their conduct does not detract from the significance of the expostulations addressed by their fellow-students at Guy's. This must be taken as indicating a strong feeling on the part of those able to judge acutely of the evil influences at work in their midst, and as such it will have weight in the minds of those who weigh the question fairly.

We should prefer to see the subject settled, and at once, by the staff. That they will be ably and generally supported, is certain throughout the country.

THE EDUCATION OF THE BLIND.

Among the important social events of the past week that of the education of the blind has excited no inconsiderable share of public attention. By the efforts of the daughter and son-in-law of the late Mr. Gardner, the munificent donor of the £300,000 for the benefit of the blind, we have had the opportunity of comparing notes, of ascertaining for ourselves what is doing in France, not only to ameliorate the condition of this class of the afflicted, but also of converting a number of them into useful members of society. No less than three large gatherings of the blind have taken place during the week, one at the Mansion House, under the auspices of the Lord Mayor of London, of the pupils of the French "Institution Nationale des Jeunes Aveugles," brought to London mainly by the generosity of Mr. and Mrs. Richardson Gardner; another at the mansion of the Duke of Westminster, of the pupils of the Normal College, at Norwood; and a third at St. James's Hall, of the teachers and pupils of the French school, with their blind director, M. Lebel.

It appears that Mr. and Mrs. Richardson Gardner were unwilling that a decision in the matter of the Gardner bequest, now in litigation before the Court of Chancery, should be arrived at before the public were made acquainted with the results of the high musical teaching accorded to the blind in the National Institution of France. The musical display was adapted to excite considerable curiosity as to what the young blind can be taught to do, and, furthermore, what their probable prospects of after-success in life. It is sufficient to say that the several performances were of a remarkable character, and that the soloists especially, both in singing and playing, displayed a thorough knowledge of music, and a firmness and decision of touch that drew forth rounds of applause from those well able to form a correct judgment.

M. Piras, whilst briefly thanking the Lord Mayor for his hospitality and kindness, alluded to the difficulty involved in the administration of every kind of benevolence, but thought none could repay society at large more fully than that of instructing the blind in useful employments and making them self-reliant. But perhaps the most valued utterance in this point came from Professor Fawcett, whose speech deserves most careful attention. It was fully reported in the *Times* of Friday last, and was no doubt largely read. It is sufficient for us to know that the views of the right hon. gentleman in every way accord with those we have enunciated, and, on more than one occasion, placed

before our readers, the chief points of which may be summarised as follows:—That the legislature, in the interest of the blind, having passed several acts making it incumbent upon boards of guardians and school boards to see to the elementary education of this class of the afflicted poor up to the age of thirteen years, it is more than ever incumbent upon charitable agencies and institutions to devote their large funds to other cases more properly belonging to charities, in giving blind children and adults the highest and best kinds of education at command. That any further charitable funds devised for the blind should be solely devoted to the training of blind teachers, the founding of workshops in which the blind may be taught and employed in all the various handicrafts of the sighted. And, furthermore, that every encouragement should be given to the perfecting and improving the various means of instruction, both mental and technical, and in establishing uniformity of system in the literature of the blind, and in improving their social position generally. To secure these ends the several asylums and institutions founded for the blind should at once be brought into harmonious working and connection, so that all may in an equal degree derive advantage from, and assist in giving effect to, the several suggestions for advancing the interests of the blind. It may be gathered from what we have said that the Gardner bequest cannot be better bestowed than upon the attainment of such important objects rather than that of building another asylum; for, of all people in the world, the blind are unsuited for aggregation; they require companionship of home-life, the friendly arm upon which they may lean for guidance and support in life.

Notes on Current Topics.

Expurgation of the Dental Register.

We observe with satisfaction that the British Dental Association is taking decisive steps towards removing from the Dental Register the crowd of chemists' assistants who have obtained admission thereto by representing themselves as "*bona fide* in the practice of dentistry in conjunction with pharmacy." The Association has sent to a number of these persons a circular, which says—"Your registration in the Dentists' Register is, in the opinion of counsel, a clear violation of the provisions of the Dentists' Act. The Representative Board therefore suggest that you should, in writing, request the Registrar to remove your name from the Dentists' Register. Should you not see fit to follow this recommendation within fourteen days from the date of this letter the Board will feel bound to bring the case before the General Council, the possible result of which proceeding will be that your name will be erased from the Register, and that you and the witness to your declaration are liable to be proceeded against under the appended section of the Dentists' Act, which was prominently printed upon your declaration paper."

The point made by the Dental Association is that no one can be in the practice of pharmacy in the eye of the law except a person qualified under the Pharmacy Act, and it is distinctly the opinion of the counsel consulted that the work done by an assistant to a chemist is not, in law, the practice of pharmacy. If this be so—and we fully believe that it is so—not one of those unregistered chemists' assistants have declared with truth that they are *bonâ fide* in the practice of dentistry in conjunction with pharmacy; and, if this be satisfactorily shown to the General Medical Council, that body must strike them off the Register *in globo*. The Council will, of course, *more suo*, try to shirk its duty in this matter, but we hope that the Dental Association will not permit such evasion, and it is satisfactory to observe that the editor of the *Chemist and Druggist* advises his constituents as follows:—

"If the Medical Council should decide against our view we would submit with a protest, for the results involved would not be worth the expense of a legal contest with such a body."

Nasal Extensors.

The London correspondent of the *Canada Medical Record* says that though probably few persons know what a "nasal extensor" is, the manufacture of such articles has become a regular part of the business of fashionable dentists in America and on the continent of Europe. Persons who are dissatisfied with their noses will be glad to hear that a nasal "extensor" is a silver lining for each nostril, the two metal forms being connected together by a yoke at the base if necessary, and the interior covered with red enamel, and by the constant use of extensors a pug nose, or, to put it more delicately, a nose that is "tip-tilted like the petal of a flower," may be transformed to any shape that its owner and her adviser consider desirable. The New York correspondent of a Cincinnati newspaper describes these inventions, and solemnly asserts that the use of nasal extensors is very common amongst the ladies of that city, and particularly affected by women to whom Nature has denied the elegant Grecian contour. It has long been understood that a determined person who is dissatisfied with his or her nose, can alter the shape, though the operation is disagreeable; but in the cause of vanity men—and women—will suffer much. A deep transverse incision has to be made across the offending pug about three-quarters of an inch above its tip, cutting through the skin, cartilage, and septum with a single clean stroke of the knife, until the edge of the instrument is on a level with the face. This done, the half-severed tip must be depressed to the proper level, leaving a triangular gap between it and the firm upper portion sustained by the nasal bones. Small, but deeply-incised, flaps are next dissected out on either side of the gap, in such a manner as to fill the vacant space, and to meet each other at the top. A nasal extensor is fitted in, the nose is trained to the desired shape, and when the scars are healed the patient is happy. Of course, all who use extensors do not undergo this operation, but without it the training of an obstinate nose in the way it should go is a tedious business.

The Functions of the Eustachian Tube.

At a late meeting of the Academie de Médecine Dr. Gellé read a paper entitled "An Experimental Study of the Functions of the Eustachian Tube." The question to be

determined is, whether the tubes are constantly open like the nostrils, or are they closed by the approximation of their walls, like the urethral canal, for instance? A question connected with this is that of the part played by the tubal and staphyline muscles in the circulation of air to the tympanum. The tympanic cavities are not resonant. M. Fournié has concluded from this that they are open, and that the Eustachian tube is the opening. But the sonorous current passes better by an open way. It follows in passing from the ear the same road which it took to get there, the external auditory meatus. With espect to cranial sounds, they find in the membrane the organ of transmission *par excellence* of sounds from solids to the air and *vice versa*. It is by this way and not by others that the sound waves make their escape. The aurist takes advantage of this phenomenon of the discharge of cranial sounds by the meatus. The blowings, crackings, and clippings have each their semiological value. Politzer invented objective auscultation, which M. Gellé has simplified under the name of transauricular auscultation. It is the analysis of the changes undergone by a sound transmitted from the cranium through the ear. The auditory meatus is then the natural channel for the discharge of cranial sounds; it is indeed the only one; the tube has no such function. Indeed Politzer, Lucæ, Tröltsch, and after them all aurists, have agreed that obliteration of the meatus, morbid or experimental, causes retention and resonance.

If it is demonstrated that by changes in the meatus the hearing is injured, it is logical to conclude that no other channel for the exit of sound exists, and that the tube has been wrongly charged with this function. M. Gellé cited twelve experiments in support of his statements.

A New Ophthalmological Society.

A NUMBER of the London ophthalmic surgeons have, last week, erected themselves into a special society, which hopes to be representative of their department of surgery. The purpose is excellent, and the gentlemen who have established the society are fully qualified to represent the ophthalmological fraternity of the great metropolis; but upon the evidence before us as to the extent of the society, it strikes us that a mistake has been made in the name which the society has selected, for we do not see upon what authority it can claim to be "The Ophthalmological Society of the United Kingdom." The United Kingdom outside London is represented in the executive of the society by one practitioner from Edinburgh, one from Dublin, and one from Leeds, the remaining sixteen officers being London surgeons. The title of the society is, therefore, somewhat redolent of Tooley Street, and its constitution seems to have been intentionally exclusive, for we observe that a motion to attach to it nine extra-London ophthalmologists was rejected, the members present electing deliberately to confine its operations—in spirit at least—to the metropolitan postal district. No doubt there is room for a London ophthalmic society, and as such we hope the new organisation will succeed, but we think it is to be regretted that the suggestion to make the society cosmopolitan was refused, and—as it has been so refused—we object decidedly to this association of London practitioners assuming to represent the ophthalmology of Great Britain and Ireland. We hope it is not too late to give the society the desired comprehensive character, and thus to enable it to serve ophthalmic science in a truly representative capacity.

The Anti-Vivisectionists

Have had their great palaver last week. Their chief talkers were Sir Alexander Malet and Lord Haldon—whoever they may be—and Lord Shaftesbury, and the usual amount of ignorance and prejudice was displayed, with the usual determination of such folk not to hear or know anything which does not tally with their own ideas. From the groaning over the unyielding nature of doctors in general, and the unsympathetic character of the newspapers, we assume that the anti-vivisectionists are beginning to find that the endless talking of nonsense is wearisome when it produces no result. It was resolved, nevertheless, to move in the House of Commons for a return of the discoveries made by means of vivisection, to be made by those who now hold physiological licences. Though we fully believe that such a return would be valuable to science, we scarcely see how Parliament or the public could be expected to understand it, and we are perfectly certain that it would produce no persuasive effect whatever upon what the anti-vivisectionists please to call their minds. However, if they like to have such a return, biologists are quite ready to give it, and have, in fact, already given it to the public through the columns of the medico-scientific papers, which the anti-vivisectors might read, if they were minded to read anything.

The Action of Quinine, Digitaline, and Atropine.

DR. GUIDO CAVAZZANI has arrived at the following conclusions on this subject (*Annali di Med. Pub.* &c.). Quinine and atropine have an astringent action on the peripheral vascular extremities. They correct the vascular dilatation caused by digitalis. Atropine and digitaline are antagonistic, the first giving tone to the terminal vessels, and paralysing the heart, the second producing an opposite effect. These two remedies associated cause considerable slowing of the ventricular contractions of the heart and much less slowing of the auricular contractions. Quinine and digitaline combined reciprocally increase their force of action. Quinine and atropine neutralise each other as to their action on the heart. These three remedies given singly may cause a state of collapse, which in quinine is due to ischæmia of the heart, in digitaline to its tetanisation, and in atropine to its asthenia.

The Naval Medical Service.

ACCORDING to the *United Service Gazette*, one of Her Majesty's ships in a home port "is in so unsatisfactory a sanitary state that a very heavy sick list appears to be her normal condition. We hear, however, that her captain has hit upon an expedient for reducing the sick list to which we might be permitted to draw the attention of the Admi-

ralty, and also that of the Royal College of Surgeons and the medical schools of the country. Sending for the fleet surgeon, the captain informed that officer, 'I'll take means to reduce it [the sick list]; you and the senior surgeon shall take turns of duty till it is of a reasonable size.'"

The action here attributed to the officer in command is of so extraordinary a kind, so closely bordering upon unreasoning tyranny, that for the present we prefer to wait a bit before considering it at length, in the hope that further details may remove the impression that the report as now given is calculated to produce. We will merely add that although inconsiderate officers really are occasionally met with in the Royal Navy, as elsewhere, still the rule is that they treat the medical officers on board their ships with courtesy. If there be an exception in the instance we allude to, we are rather inclined to attribute it to the individual than to "the system"—but perhaps more on this head in our next.

Arsenical Wall Papers.

In a recent case which was tried at Guildhall, Messrs. Steinhoff sued the defendants, Messrs. Woollams, wall paper manufacturers, for sums due for colours supplied to the latter. Defendants refused payment, on the ground that the colours were verbally guaranteed by the plaintiff's agent as non-arsenical, whereas one of them did, in fact, contain a large quantity of arsenic. Defendants had used the pigment in the manufacture of wall papers, and as it has been a strict rule with them for years past to allow no arsenical colours to be used in their factory, they were thrown between the alternatives of endangering their reputation by the sale of goods detrimental to the public health, or of having the stock of arsenical paper they had unwittingly manufactured left on their hands. They now made a counter claim on the plaintiffs for £370, as compensation for the loss incurred.

The traveller to the plaintiff, denied most positively that he had guaranteed the "Imitation Azure Blue" to be free from arsenic.

The jury found for the defendants, the amount of damages to be settled by arbitration.

The Alleged Famine Fever in the West of Ireland.

We had before us last week reports of the fever at Swinford and its neighbourhood, which led us to believe that the epidemic was one of ordinary typhus, and not in any sense attributable to famine. We did not publish these reports because they did not conclusively prove that the disease was not famine fever, and because we did not like to encourage those who wished to use this outbreak of fever as a political cry for the purpose of getting money from Parliament. Dr. Grimshaw, the Registrar-General for Ireland, has since then definitely stated that the epidemic was not one of famine fever. The Local Government Board for Ireland has, however, at the instance of the Chief Secretary for Ireland, decided to investigate the matter for themselves, and have consequently sent Dr. Stewart Woodhouse, of Dublin, down to Swinford to investigate and report. We understand that Dr. Nixon—the recently appointed physician to the Lord-Lieutenant of Ireland—has also been asked to inquire into the matter, and to report to the Local Government Board, and that he leaves Dublin immediately for the West of Ireland.

The Treatment of Diphtheria.

Dr. Bloch (*La France Médicale*) has long employed, as his principal treatment in diphtheritic angina, dry cubeb pepper applied to the throat by means of a brush, and has obtained from it excellent results. He orders the application to be made every hour, with the administration of liquid food, wine, bark, &c. The false membranes are detached and not reproduced. The application causes retching—sometimes vomiting.

These contractions of the pharynx are probably one of the elements of success. The absorption of the cubebs which the patients swallow also acts; this remedy has long been administered internally in membranous angina, and with satisfactory results. Lastly, the topical substitutive action has an important part in the happy effect of this treatment. It is easily used, and parents can themselves apply it to their children's throats. In catarrhal and pultaceous angina the same treatment succeeds marvellously—much better than alum, chlorate of potash, borax, tannin, &c.

Sleeplessness.

The following is recommended as cure for sleeplessness: Wet half a towel, apply it to the back of the neck, pressing it upwards toward the base of the brain, and fasten the dry half of the towel over so as to prevent the too rapid exhalation. The effect is prompt and charming, cooling the brain and inducing calmer, sweeter sleep than any narcotic. Warm water may be used, though most persons prefer cold. To those who suffer from over-excitement of the brain, whether the result of brain work or pressing anxiety, this simple remedy has proved an especial boon.

Pensions in Irish Lunatic Asylums.

We are glad to perceive that the suggestions which appeared in our "Lunacy" column on June 1 promise to produce some fruit. A memorial to Lord O'Hagan has been set on foot, showing the disadvantageous position in which the medical and other officers of our Irish asylums are placed as regards pensions, and respectfully requesting him to deal with the matter in the Bill which he is about to introduce relative to the treatment of the insane poor. The memorial tabulates the grievances to which we drew attention in our article.—1. That the period of service must amount to forty years before a two-thirds pension is payable, while in England a two-thirds pensions is payable after fifteen years. 2. That the whole period of service is required to be spent in one asylum, whereby men of experience are prohibited from accepting promotion. 3. That by reason of being paid from local rates, medical officers who have spent many years learning their profession and their specialty are unable to claim the benefits of the "Special Service" clause of the Civil Service Act.

A Cure for Snake Bite.

Mr. Tremlett, Consul for Saigon, furnishes some further notes respecting *hwang-nao*, which is said to cure the bite of the most venomous serpents, and has been successfully employed in curing cancer, and principally leprosy, in the treatment of which it has never given other than satisfactory results. The native physicians, Mr. Tremlett tells us, distinguish thirty-six kinds of leprosy, the most common attacking the feet and hands ; it is considered to be hereditary, and is usually contracted by children at the age of puberty. After some generations, it has been noticed to confine itself to either the male or the female members of the family ; the disease is considered contagious, which only would account for the number of lepers in Tonking.

Indican in the Urine of Typhoid Patients.

A patient under the care of M. Hardy (*Le Praticien*) was attacked with fever and diarrhœa, which suggested typhoid ; however, the fever soon ceased, the temperature fell to normal, and it was supposed to have been only a synocha. There still remained, however, a certain amount of swelling of the spleen and of diarrhœa which tended to support the first diagnosis. About the fourteenth day there appeared some spots which were only discovered with difficulty. In order to find a new element of diagnosis, M. Hardy examined the urine of the patient for indican, the blue matter which sometimes exists there.

To discover this a few grammes of urine should be put into a test tube, three times its volume of hydrochloric acid added, and then slightly warmed. The mixture must now be cooled, and a few grammes of ether added. The cooling is necessary on account of the great volatility of the ether ; if it be put into warm liquid an explosion may occur. The mixture of urine and ether should now be agitated by closing the mouth of the tube with the thumb and inverting it a few times. The ether being lighter than water will separate and collect at the top, and if indican is present, as was the case in M. Hardy's patient, there will be found a perfectly characteristic blue ring. This presence of indican in the urine, which is very easy to discover, is not, however, a pathognomonic sign ; it may be present in the urine of those suffering from other affections or even in good health, but it is a useful sign when added to those furnished by other symptoms.

The Secretaryship of the Royal Irish Academy

Which is generally regarded as one of the highest scientific positions in Ireland for active scientific men, has been given to Dr. MacAlister, Professor of Anatomy and Chirurgery in the University of Dublin. He succeeds Dr. Ball, the Astronomer Royal for Ireland.

The New Councillors.

The Council election at the Royal College of Surgeons of England took place last Thursday, the result being that Messrs. Cadge, Bryant, Lister, and T. Smith were chosen to fill the four vacancies. The latter gentleman having secured the smallest number of votes, will hold office for four years only, the charter of the College providing that a substitute member of Council elected to replace one who retires other than by rotation shall continue to hold office only so long as the tenure of it would have remained with the member whose place he fills. Mr. Simon, the retiring member, would have resigned in due course in 1884. The following is the complete list, with the number of votes recorded for each :—Mr. Cadge 174, plumpers 14 ; Mr. Bryant 170, plumpers 15 ; Mr. Lister 169, plumper 1 ; Mr. T. Smith 136, plumpers 13 ; Mr. Hulke 107, plumpers 6 ; Mr. Adams 87, plumpers 6 ; Mr. Hill 51, plumpers 6 ; Mr. S. Jones 45, plumpers 4.

The Normal Condition of the Eustachian Tubes.

At a recent meeting of the *Société de Biologie*, of Paris, M. Gellé expressed the opinion, the opposite of that recently put forward by M. Fournier, that in the normal state the Eustachian tube is closed. He gives the following reasons based on his experiments : If the tube is open a vibrating tuning-fork placed in the mouth should be heard even when the ears are closed. Now that is not the case. It is, nevertheless, possible to hear by the tube when the ears are closed, but only in cases where by a swallowing movement the tubes are opened. Hartmann found that to overcome the closure of the tube, and permit the air to penetrate to the tympanum, a pressure equal to from twenty to forty millimetres of mercury was necessary. M. Gellé has found that from thirty to forty millimetres are required.

Water and Typhoid.

The *Leisure Hour* magazine, published by Messrs Cassell, Petter and Galpin, contains some useful hints to tourists with respect to drinking water. It mentions a case of typhoid terminating fatally at Dinan in Normandy last year. The victim was a tourist, who was seduced into drinking freely at a hotel water which seemed bright, clear, and delicious. It cannot be too urgently impressed on intending visitors to the country and seaside that there is frequent danger lurking in their path, and that it will need the exercise of constant wariness to enable them to escape the snares that will beset them. Impure water and ill-ventilated rooms are the especially prevalent evils, and too much guardedness cannot be employed against them.

Trephining of the Tibia for Neuralgic Osteitis.

At a recent meeting of the Société de Chirurgie of Paris, M. Delins read the case of a young man, æt. 21, who was admitted under his care suffering from pain in the extremity of the right tibia with swelling of the bone above the tuberosities. He had suffered for five years, especially at night, and his rest was disturbed. He had signs either of sclerosis, of encysted abscess, or perhaps simply of neuralgic osteitis. On April 28, the crown of a trephine was applied to the inner surface of the tibia. The bone was thickened, eburnated to a thickness of 28 millimetres. No cavity full of pus was found as expected, but only a very vascular spot. This was removed with a gouge, and then a cavity was found full perhaps of serous liquid, but containing no pus. Was

this a cavity or an extension of the medullary canal? From the first night the patient slept, and the cure has continued to the present time.

A New University College.

THERE seems every prospect that a new University College is about to be added to the already long list of centres of higher education in this country. The Liverpool people, stimulated probably by the example set in Manchester by the Owens College, have decided that they too need an *alma mater* for their descendants, and already very considerable support has been given to the scheme. £60,000 has been subscribed for the establishment of the college, several sums of £10,000 each having been contributed by single donors. It is gratifying that the excellent teaching schools founded in Leeds, Bristol, and Birmingham have been so successful; and there can be but little doubt that the new one at Liverpool will not be eclipsed in results by its older sisters, when once in working trim.

Hypodermic Injection of Chloroform in Sciatica.

DR. BLACHE directs, in *L'Union Méd.*, May 11th, 1880, that the first injection of pure chloroform be made at the highest point of the seat of pain, throwing in a syringeful, or about one gram and a fifth. Next day the injection should be made lower down, and the third day lower still. In certain cases even two or three injections may be made the same day, thus inserting three or four grams of chloroform. In obstinate cases Dr. Besnier advises the injection of an entire syringeful at the highest point, a second opposite the great trochanter, a third near the head of the fibula, and a fourth at the malleolus. If the pain has not disappeared at the end of three or four days, recourse should be had to other means of treatment.

General Medical Council.

THE annual summer meeting of the General Medical Council will commence on Wednesday next, the executive council being summoned for Tuesday to decide the order of business. From appearances, the meeting is not likely to be a prolonged one, unless the discussions on certain points should be unduly protracted. The stagnation in respect to legislation on the subject of medical education may be expected to influence the Council's proceedings in some respects, though it cannot have much effect in lengthening them. The probable shortness of the session will be hailed with satisfaction by more than the gentlemen who assemble at such an inconvenient period of the year.

A Park for Croydon.

THE Croydon Local Board of Health have shown a wise forethought in purchasing a piece of land measuring seven acres, in Park Lane, Croydon, to serve as an ornamental park for the inhabitants of the neighbourhood. An estimated cost of £14,000 is named as the amount required to completely convert the ground, money which will be amply repaid in the benefits of healthy recreation that will accrue from the possession of the new park.

Bacterium Fœtidum.

DR. GEORGE THIN communicated a paper to the Royal Society recently on "An Organism associated with Profuse Sweating from the Soles of the Feet," in which he demonstrated that the peculiarly offensive fœtid odour by which the secretions from the skin of certain people's feet is characterised, is due to the development in the liquid, after secretion, of a micrococcus which the author names *Bacterium fœtidum*. He asserts that perspiration is odourless when it soaks to the sock, but that once there it rapidly acquires the peculiar smell. The fluid is, he says, an admixture of sweat with serous exudation from the blood, occurring in persons whose feet sweat profusely, and who, from much standing or walking, acquire an erythematous or eczematous condition of the soles of the feet. Dr. Thin pursued an elaborate series of investigations into the history of the development of the organism, during which he convinced himself that by antiseptic means the micrococcus can be killed and the disagreeable odour at the same time destroyed.

The Relation between Cardiac and Renal Affections.

AT a recent meeting of the Société Médicale des Hôpitaux Dr. Debruc discussed this question *àpropos* of two cases he had recently observed. In the first patient, whose death was due to the impaction of a piece of meat in the pharynx, the heart was found enlarged, weighing 750 grammes. The hypertrophy was almost exclusively limited to the left ventricle. The kidneys at first appeared normal. Histological examination, however, showed fibrous degeneration of the heart and interstitial nephritis. In the second case the patient died of pneumonia, and the heart was slightly enlarged, but almost normal, but the kidneys showed marked evidence of extensive interstitial nephritis. In the first case the disease had evidently commenced in the heart, in the second in the kidneys, and these two cases seem to prove that if cardiac affections may be consecutive to renal disease the reverse may also obtain.

Acid Reaction in Animal Tissue.

MARIE EKUNINA describes, in the *Journal für Praktische Chemie*, an investigation conducted in Prof. Nencke's laboratory at Berne, on the causes of acid reaction of the animal tissues after death. This reaction is attributed to the decomposition of tissue juices, after death, by fungi. Volatile fatty acids first arise through commencing decomposition of albumen, but very soon the two lactic acids proceeding from glycogen are associated with these. The richer the tissue in carbo-hydrates, the longer does the acid reaction continue after death; this is especially the case with liver, muscles, and lungs. The shortest and weakest acid reaction is that in the pancreas. Sooner or later, in all tissues, the acid reaction passes over into an alkaline, while the decomposition of albumen increases, and there is much formation of ammonia.

Charcoal in Typhoid.

IN the *Lyons Médicale*, May 23rd, it is stated that Dr. Bouchard finds the administration of pure charcoal powder

in typhoid fever very favourable, that it causes the fœtid odour of the stools to disappear, prevents absorption of putrid matter, cleanses intestinal ulcers, and does not cause hæmorrhage or other accident. The dose given is a tablespoonful every three hours.

A Homœopathic Dodge.

THE *New York Medical Gazette* says that some six months ago its attention was called, by one of the inmates, to certain abuses which were being carried on in the Homœopathic Hospital at New York. It has of late been investigating the charges, with a view of collecting proof sufficiently overwhelming to justify the bringing the matter before the legislature, but the ubiquitous newspaper reporter has given the whole story to the public rather prematurely. Here it is :—

On Ward's Island is the Homœopathic Hospital. The building used for this hospital was originally built in the time of the Tweed Ring, and fabulous amounts of money have been squandered upon it. A tremendous political pressure was successfully brought to bear on the Commissioners to furnish the building for the homœopaths. This was the first public hospital ever secured by the homœopaths, and it is costing the taxpayers of the city 60,000 dols. a year. The homœopaths, so it is alleged, discovered that the convalescent patients at the other hospitals got passes to go to and from the city, and at once utilised this discovery. Instead of giving passes the applicant is told to go, and when returning to call at the Commissioner's office and get a new permit. Thus, it is said, the same patient often counted as two, three, four, or more patients admitted. Numbers of them were sent out in this manner a dozen times. By this means the admissions and discharges (as cured) were increased 300 per cent., and the percentage of deaths of course was correspondingly low. The mortality in the three leading hospitals the first year after the Homœopathic started was—Bellevue Hospital, 12½ per cent.; Charity Hospital, 8½ per cent.; Homœopathic Hospital, 6 per cent. On the publication of this result homœopathic organs grew jubilant. The same course was pursued the ensuing year, and the result (on paper) was about the same, while all the time the actual percentage, it is declared, was about 18. After nearly three years of this adroit management the Commissioners began to find it very troublesome to be issuing so many fresh permits to the same individuals, so an order was issued to let parties wanting passes have them. But the homœopaths were equal to the emergency, and the next device, it is alleged, was to discharge the sick and keep the healthy in the building. This piece of strategy, it is said, has been carried out during the past year, and when the annual report for 1879 is published, the mortality report of the Homœopathic Hospital will once more appear (on paper) astonishingly low.

Cæsarean Section Extraordinary.

THE *Wiener Med. Wochenschrift* gives the following anecdote, on what appears to be unquestionable authority. A poor woman at Prischtina, not far from the Servian frontier, was in the pains of labour for three days, but to no purpose. In her perplexity she seized her husband's razor, cut open her abdomen and uterus, and got a neighbour to sew her up again, after the removal of the child ! And now, after several months, mother and child are doing perfectly well.

DR. WM. B. CARPENTER will visit the United States during the summer.

SCHLAEFKE, in *Graefe's Archiv.*, records the fact that if calomel be applied to the eye, and iodide of potassium administered internally, severe inflammation of the conjunctiva is liable to arise.

ONE Haywood, an unqualified medical practitioner at Birmingham, has been charged with the wilful murder of a single woman, twenty-four years of age, who died, as alleged, from an attempt of the prisoner to procure abortion.

We believe we are right in supposing that this memorial will be signed by all the asylum officers in Ireland, and we think it cannot fail to carry much weight, both with the distinguished individual to whom it is addressed and also with the Government.

DR. KOLLER, in *Pharm. Ztg.*, reports that he has found glycerine applications equal, if not superior, to the sodium bicarbonate, about which so much has been written for severe burns. He applies the concentrated, syrupy, perfectly clear glycerine to the burn without pressure.

THE Committee of Management of the Metropolitan Convalescent Institution have had placed at their disposal the sum of £6,500, on condition that they at once add to their institution a seaside branch. This it is proposed to do at a cost of about £12,000, and the Committee appeal for funds with which to support the branch establishment.

A PERSON, named Lewis Smith, was summoned before Hyde County Court, Cheshire, by the Apothecaries' Society of London, for having practised as a medical man at Hyde, without possessing the necessary qualifications. A fine of £20 and costs were inflicted upon the said Lewis Smith, who, we should imagine, will try some other art in which such penalties are unknown.

ON Saturday the annual visitation and inspection of the Leavesden Imbecile Asylum was made by the managers of the Metropolitan Asylums District, who pronounced everything to be in a most satisfactory condition. At the present time the number of inmates consists of 890 male and 1,096 female patients—together 1,986, rather below the average.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Brighton 13, Bristol 14, Norwich 15, Plymouth 15, Salford 16, Bradford 17, Hull 17, Portsmouth 18, London 18, Sheffield 18, Birmingham 19, Wolverhampton 19, Leicester 19, Leeds 19, Glasgow 20, Edinburgh 21, Newcastle-upon-Tyne 21, Sunderland 21, Nottingham 23, Liverpool 24, Manchester 24, Oldham 27, Dublin 33.

THE death-rate in the large towns last week from the seven principal zymotic diseases ranged from 0·7 and 0·8 in Wolverhampton and Leicester, to 5·6 in Salford, 7·6 in Sunderland, and 8·0 in Dublin. Scarlet fever showed the

largest proportional fatality in Salford, Bradford, Sunderland, and Newcastle-upon-Tyne; measles in Oldham and Sunderland; and whooping-cough in Liverpool, Manchester, and Birmingham. Small-pox caused 14 more deaths in London, 19 in Dublin, and one in Manchester, but not one in any of the other large towns.

By telegraph from New York we learn that extremely hot weather has prevailed in the Eastern States for several days. Forty-six deaths from sunstroke occurred at New York on Monday and Tuesday. Although at present we are not experiencing such broiling heat in this country, the past few days' sun has been nevertheless sufficient to draw our close attention, and probably that of many of our readers, to the instructive series of articles on "Sunstroke in India" now appearing in our columns from the pen of Surgeon-Major Curran.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 20, Bombay 30, Madras 36; Paris 27; Geneva 25; Brussels 27; Amsterdam 21, Rotterdam 22, The Hague 22; Copenhagen 21; Stockholm 25; Christiania 21; St. Petersburgh 53, Berlin 33, Hamburg 25, Dresden 25, Breslau 33, Munich 35; Vienna 31, Buda-Pesth 42; Naples 33, Turin 29, Venice 20; Alexandria 52; New York 32, Brooklyn 24, Philadelphia 21, and Baltimore 27 per 1,000 of the populations. Small-pox caused 51, and typhoid fever 27 deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Faculty of Physicians and Surgeons of Glasgow.—It is understood that at their first meeting, on Monday, the 5th inst., an expression of opinion will be asked from the Fellows of the Faculty as to the propriety of inviting the British Medical Association to Glasgow. It is not supposed that the response will be entirely favourable, as the subject is not a popular one with the Faculty.

Visit of Trade Representatives to the Broomhill Home for Incurables.—By invitation of Miss Clugston, between one and two hundred representatives of trades in Glasgow, on Saturday, the 3rd inst., paid a visit of inspection to the Broomhill Home for Incurables at Kirkintilloch. An entertainment was provided for them in a tent on the grounds, and Miss Clugston explained her scheme for the extension of the Home, in which she is desirous of interesting the working classes of Glasgow and the country generally.

Lord Rectorship of Glasgow University.—It is stated that Mr. Ruskin has consented to be nominated for the Lord Rectorship of the University of Glasgow by the Conservative and Independent Clubs, and that, if elected, he will deliver the usual address. The Liberal nominee is Mr. John Bright, whose name was brought forward before that of any other candidate.

Accidental Poisoning at Dalry.—On Saturday, the 26th ult., a widow woman, residing in Dalry, was accidentally poisoned by swallowing a quantity of carbolic acid. It appears that the poor woman's daughter had died on the previous day from fever, and a bottle of carbolic acid had been procured for disinfecting purposes. This the deceased placed alongside some ginger-beer, and on going to take a drink of the latter she accidentally partook of the acid. Medical aid was called in, but owing to the swelling in the mouth and throat the stomach-pump could not be applied. The unfortunate woman died the following day.

Bequest to the Royal Infirmary, and the Western Infirmary, Glasgow.—By the will of the late Mr. Dixon, of Govanhill, who is reported to have died worth two millions sterling of money, the Glasgow Royal Infirmary and the Western Infirmary get each £5,000, which is, however, to be transferred to a hospital for the South-side, in the event of one being built there. A movement in this direction was agitated some years ago, and doubtless this windfall of £10,000 will cause a revival of the scheme. No more new hospitals are at present spoken of.

Outbreak of Enteric Fever at Possilpark.—Dr. Christie, medical officer of health for Hillhead, has just prepared a report showing that the recent outbreak of enteric fever in Possilpark, like that in the city, was due to contaminated milk.

A Medical Man's Jubilee.—A number of the friends of Dr. Lyon, who has been a medical practitioner at Peterculter for the long period of fifty years, have resolved to present him with a testimonial on Friday, the 23rd inst.

Death of Dr. Lawrence, Longside.—After fifty years' practice in the district of Longside, Dr. Lawrence has just died. He was greatly esteemed as a medical adviser, and much respected for his personal qualities. Eight years ago he was entertained to dinner by members of the Buchan Medical Society and other professional brethren, the company numbering about sixty.

Registrar-General's Returns. — According to the weekly return of births, deaths, and marriages in the eight principal towns of Scotland, the death-rate for the week ending with Saturday, the 26th June, was 20·5 per 1,000 of estimated population. This rate is 0·1 below that for the previous week. The lowest mortality was recorded in Greenock, viz., 13·1 per 1,000, and the highest in Perth, viz., 27·3, and in Paisley, 27·6 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·8 per 1,000, slightly lower than that for last week. The number of deaths from whooping-cough is considerably less, but an increase occurred in the number from diseases of the bowels. The death of a male, 25 years of age, occurred in the Royal Infirmary, Edinburgh, from hydrophobia. Acute diseases of the chest caused 79 deaths, being 9 less than the number recorded during the previous week.

Literature.

THOROWGOOD ON THE HYPOPHOSPHITES IN CONSUMPTION. (a)

Dr. Thorowgood is well known as a worker in the field of investigation of the therapeutics of lung diseases. Any remedial agent which appears likely to aid us in the treatment of any of the Protean forms of phthisis deserves careful study, and every endeavour should be made to arrive at a correct estimate of its true value. This is especially the case with regard to the hypophosphites, which were introduced with a great flourish of trumpets as specifics for phthisis.

(a) "On Consumption and its Treatment by the Hypophosphites." By John C. Thorowgood, M.D. Lond., F.R.C.P., &c., &c. Third Edition. London: Baillière, Tindall, and Cox. 1880.

Like the majority of specifics, however, they were unable to stand the fire of careful and exact experiment.

Dr. Thorowgood early began to investigate the action of these preparations, and gave his results to the profession some years since in the first edition of this work. Since that time many other careful observers have recorded their experience.

In the present edition the author gives us details of numerous cases in which he has given the hypophosphites, and from them deduces the conclusions at which he has arrived as to the forms and stages of the disease in which these agents will be found beneficial. These conclusions may be said in the main to agree with those arrived at by other observers; and would appear to show that the hypophosphites exert a decided curative action over the product of inflammatory processes in the lungs.

In the tubercular forms of the disease also, in the early stage, the combination of the hypophosphites with favourable conditions of climate, seems to increase the probabilities of recovery. It would seem by no means unlikely that this good effect is caused by the hypophosphites increasing the aptitude of the system for absorption of oxygen, as suggested by Dr. C. J. B. Williams.

With regard to the administration of the hypophosphites, Dr. Thorowgood prefers to give them in as simple a form as possible, a simple aqueous solution often appearing to produce as good effects as when the salt is combined with other remedies.

Dr. Thorowgood's little book should be studied by all who are interested (and who of us is not?) in the advancement of our knowledge of the therapeutics of consumption.

CHEMISTRY. (*a*)

The phrase "Introduction to the Study of Chemistry," used as a title to this work, is somewhat indefinite, because there are various opinions as to what style of information is best suited as an "introduction." In the present instance the author is evidently of opinion that, at all events, for learners who are advanced beyond schoolboy days, the leading principles and theories of the science cannot be introduced too early into their studies. The whole of this little book is therefore given up to theory—to the explanation of the atomic theory, atomicity, "bonds" and radicals, formulæ, and the mysteries of chemical nomenclature and equations. The manner in which the author has explained these difficulties is nearly always clear as well as accurate, and is, in some cases, distinguished for considerable neatness and novelty. We think the work is likely to be exceedingly useful to the medical student; and if carefully studied, and the information utilised in noting the results of practical experiments, it is likely to give him a ground-work considerably above the average. The book, however, would have been improved by more system in the use of the capital headings, and by the use of subject-heads at the top of the pages.

EXPERIMENTAL RESEARCHES IN PURE AND APPLIED AND PHYSICAL CHEMISTRY. (*b*)

If a writer has been a true worker in the subjects of which he discourses his book will be always read with interest. That Dr. Frankland has been an indefatigable worker in the science of chemistry no one will deny, and the thousand and odd pages before us place this fact strikingly before the reader.

The first part of the work deals with the system of notation which bears Dr. Frankland's name, and which is now familiar to most of our chemical readers. We do not believe this system will outlive the author's time; and outside the schools, where the author conducts the examinations, it has not received the support which a really useful system could demand. At the same time its author is strong in his opinion, and states in his introductory remarks, "that by means of this method students arrive at the same point in their curriculum in about two-thirds of the time necessary under the older system." If such were the case it would be a most powerful argument for its general adoption; but one of the weak points of the system is that it teaches as fact certain formulæ for which there is no data.

We think Dr. Frankland has arrived at his deservedly high position by important practical discoveries, of which we have abundant evidence in the volume before us. We would specially mention the discovery and isolation of the organic radicals, ethyl, amyl, also the synthesis of the organo-metallic bodies, a long series of most successful discoveries which have had a marked bearing on the progress of organic chemistry generally. These researches alone are quite sufficient to establish the author's fame — "Researches on the Lactic and Acrylic Series."

In the practical part of the work the author's various papers in connection with the analysis of, and purification of water, will be read with interest, not only because the author is the inventor of a process of analysis which gave rise to the Wanklin-Franklin war, but because its author has done most of the work for the Registrar-General, the Rivers Pollution Commission, and also for the Metropolitan Water Companies. Dr. Frankland's papers on the Source of Muscular Power, Climate, and many others, will be read with interest by the subscribers to this journal.

(*a*) "Introduction to the Study of Chemistry." By A. P. Luff, F.I.C., F.C.S., F.L.S., &c. London: J. and A. Churchill.

(*b*) "Experimental Researches in Pure and Applied and Physical Chemistry." By E. Frankland, Ph.D., F.R.S., &c. 1878. London: John Van Voorst.

Correspondence.

FRATERNIZATION WITH HOMŒOPATHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Of course, if the College of Surgeons of Ireland chooses to pass any resolution not absolutely illegal it is free to do so, but surely it is hardly consistent with the dignity of a college to inflict a wanton insult on those of its members who are guided in practice by a therapeutic rule the majority of its members do not believe in. Does a belief in this rule warrant the College in stigmatising the system the minority of its members follow as quackery, and those members quacks? What ground has the College for speaking of homœopathy as a deception? Surely there are text-books and treatises on homœopathy in abundance where the system is explained in the clearest possible manner. The principles of homœopathy are perfectly well known to the profession and the public. They are: 1. The testing of drugs on the healthy human body in order to ascertain their physiological effects; 2. The selection of a medicine for curative purposes whose physiological effects on the healthy correspond with the morbid phenomena of the disease to be cured; 3. The prescription of one remedy at a time; 4. The administration of the remedy in a dose not strong enough to excite its physiological action, but sufficiently strong to cure the disease.

I put it to your fairness and sense of justice to say if a method of treatment such as this is, about which there is no concealment whatever, but, on the contrary, rather an excess of eagerness on the part of its practitioners to make it generally understood, can with propriety be designated a deception, and those duly-qualified members of our colleges and universities who practise it be appropriately called quacks.

If the College desires to prohibit those of it fellows and licentiates who are not convinced of the truth of the homœopathic therapeutic rule from consulting with those of its fellows and licentiates, and the fellows and licentiates of other colleges, who are so convinced, can it not say so without needlessly insulting those it objects to as consultants by telling them without a shadow of proof, in fact, in direct opposition to all proof, that the treatment they pursue is deception and quackery?

If the College has any proofs to offer that the homœopathic therapeutic rule is false and unscientific, we shall be glad to see those proofs, for we are not so wedded to a therapeutic system as to continue to uphold it after its falsity has been proved. But surely the College does not suppose that its mere unsupported allegation that homœopathy is a deception and a quackery will make it so.

It is not surely considered gentlemanly conduct to call persons of your own status (or, indeed, of any status) opprobrious epithets if you wish to cut them. Is a College exempt from compliance with the rules that all gentlemen consider themselves bound to obey?

Is the College not pronouncing judgment on a matter of

scientific opinion in denouncing a system of therapeutics they have not examined, and which the majority of their members do not practise, as a deception and a quackery? And is it not somewhat inconsistent on your part to inveigh against those who believe and practise according to the homœopathic therapeutic rule as persons with whom it is dishonouring to hold professional intercourse, whilst in the very same number you commend as an "instructive and valuable book" a work on Hay-fever written by a practitioner of the system you hold up to reprobation? Your obedient servant,

R. E. DUDGEON, M.D.

53 Montagu Square, London,
July 2, 1880.

CHLOROFORM [*v.* ETHER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly inform me in the next issue of the *Press* what is the opinion (as far as it has been ascertained) of the profession in general as to the relative safety of chloroform and ether as anæsthetics?

I am, Sir, yours, &c.,

ENQUIRER.

Limerick, 28th June, 1880.

[So far as we can judge there is no doubt in the mind of the profession that ether is very much safer than chloroform, if not absolutely devoid of danger. But it is, in some respects, less convenient, and therefore does not meet with favour on the part of busy surgeons.—ED. M. P. & C.]

CHEAP DISPENSARIES.—No. I.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Such sweeping censure, I might almost say indiscriminate abuse, has of late been levelled through the columns of some of your contemporaries at cheap self-supporting dispensaries—and strange to say without eliciting one word in their defence—that in the name of fairness and in the unfortunate default of any one better qualified than myself to undertake the task, I beg such indulgence of your space as may enable me, if not to meet all the hostile criticism which has been showered upon them, at least to show that there may be another side to the question, that there may by chance be some fallacy in the assumption that these dispensaries are without exception the fountains of evil which we have been assured they must be.

It would be impossible to notice all the grounds of the unfavourable opinions which have been so lavishly expressed; but the following seem to be the most important of them: It is contended that under this system the practitioner sells his educated talent regardless of its value, a practice incompatible with the slightest respect for his dignity or regard for his interests, and leading, should its operation extend, to an internecine competition, disastrous to the welfare of the profession, and which must ultimately deprive medical skill of any market value at all. These arguments, however, which treat of the matter as a mere trade or commercial question, would very imperfectly represent the views of a large number of people in whose opinion a profession is properly the jealous guardian of a cherished monopoly, the maintenance of which involves a closer bond of union than the ties which unite society at large; and as family obligations rank before public duty, and patriotism is esteemed more highly than cosmopolitanism, so even such laudable objects as general convenience and public benefit should never for a moment overshadow the sacred allegiance every member owes to his profession—a praiseworthy sentiment which, according to the pessimist views, dispensaries are likely to entirely annihilate.

Lastly, it is insisted that by no possibility can proper medicine, let alone advice, be furnished for such a sum as sixpence, or even a shilling, so as to leave even the smallest margin for profit, and it only remains to determine whether a practice which undertakes to do this is a charity or a fraud, the inference from which is sufficiently obvious.

To one or other of these groups most of the objections that have been put forward may be referred, and if they are as correct as they are decided, the system to which they apply stands condemned at once as a commercial blunder, a professional scandal, and a public fraud—a withering blast of censure which ought to severely test the vigour of the noxious weed it seeks to uproot.

But before acquiescing in this sweeping verdict it will be fair to examine briefly the accuracy of the premises and conclusions deduced from them on which this opinion has been founded.

To take first the professional aspect of the question, which is perhaps the direction in which personal feelings find most scope—admitting fully the importance of that mutual loyalty and reverence for the interests of the fraternity which should characterise its members, and to which I have alluded, it seems no less important to recognise the fact that the real interests of the profession must harmonise with those of the public, whose servants they are; and if it could be shown that the machinery in use had become obsolete and inadequate to meet the growing needs of changing circumstances, that it was tending to engender and foster abuses, the welfare of all concerned would be best promoted by judicious reform, not by unbending conservatism, whose exclusive adherence to the narrow interests of a class, would ultimately defeat its own object, and must end in signal failure and ignominious collapse.

That an occasion something like that here indicated has arisen at the present time I propose to show. A rigid maintenance of what has been commonly considered a proper fee for medical advice is utterly inadequate to meet the requirements of a large section of the community, and necessitates a monstrous system of medical relief maintained by misappropriated charity supplied by a credulous public who are furnishing support, not as they are taught to believe, solely to the urgent necessities of the deserving poor—half the money properly applied would suffice for that—but to an unlimited crowd of amateur paupers, to any person whatever, in short, who is shameless enough to accept an alms to which he has not a vestige of title, and which is nothing short of a scandal and a disgrace to promoters and recipients alike.

It is impossible that this evil can be met in any other way than by some system which brings medical relief within the reach of the working classes at a sum which they can afford, without branding them as paupers. And there can be little doubt that by properly managed dispensaries, either public or private, it is possible to effect this, sufficiently for the wants of the classes referred to, advantageously to the medical men who attend them, and without prejudice to the interests of the profession at large.

If effect were to be given to the views which have been strenuously advocated by a section of those with whom I join issue, and medical men were to agree never to charge a smaller sum than 5s. for advice, this charity scandal would assume far greater proportions than it has reached yet, a consummation which may be guessed at by looking at its extent now; when, according to evidence brought before a commission appointed by the British Medical Association some time since, no less than one million persons received gratuitous medical relief in one year in the metropolis alone. This may somewhat overstate the actual case, as some of the patients may have had more than one illness in the year, and have been counted more than once, but after making every allowance for this, the result is sufficiently startling. At one hospital (St. Bartholomew's) the reporter saw over 100 patients treated (?) by one doctor in less than an hour, the medicine being poured without fear or favour out of a large jug, and at some other hospitals the numbers being beyond even this high-pressure capacity of the proper officer, a considerable proportion were relegated to students, and not all of these were senior students either, and an instance was reported of a medical officer being dismissed for refusing to prescribe for new patients at the rate of 100 per hour.

This state of things fully deserves the description of the Chairman of the Charity Commission, who characterises it as a disgrace to the profession and a fraud upon the public, and that any one can be found to approve of and to wish to increase and extend it, is an illustration of the principle that there is no system so bad as to find no supporters, and its continuance is mainly due to the superstitious terror of that nightmare of innovation and reform which haunts many members of the medical profession, for whose weaknesses the public have so generous, though it may be, an unconscious consideration.

Your obedient servant,

A. B.

THE GENERAL MEDICAL COUNCIL.

To-day the Council commences its sitting, which seems likely to be uneventful. There does not appear to be much business of importance for transaction, and, as the lethargy of approaching dissolution has settled down upon the Council, we anticipate that there will hardly be much energy in that body to perform even what needs to be done. It is hardly to be expected that the members will care to enter with interest into questions of curriculum and examination, inasmuch as what it might now settle would probably be disturbed within twelve months, and as to disputed points in reference to licensing and registration, and the constitution of the Council itself, these are already in course of adjustment outside, and it is not probable that the result would be much affected by anything that the Council could say or do.

The minutes of the Executive Committee, which met, in anticipation of the assembly of the Council, on the 16th of June, are singularly void of interesting matter. The dispute as to whether alterations of address or additional qualifications shall be registered in the branch at which the original registration was effected, or at head-quarters, in Oxford Street, has been decided, practically, in favour of the Irish Branch which was contesting the question, Mr. Ouvry, the solicitor of the Council, having advised that the local registrars were entitled to perform this duty. The matter is of importance only because the local registrars have been enabled thus to assert the individuality of their offices, and *pro tanto* to defeat the tendency to centralisation of the registration business in London, which was sought to be effected by a clause in the Duke of Richmond's first Medical Bill.

Amongst the other business before the Executive Committee we find the following interesting item :—

"8. *Read.*—Letter from Mr. Chappell, who, in May, 1879, made a former application for registration, requesting to be allowed to be registered by virtue of a diploma purporting to confer the degree of M.D., 1849, of the University of Aberdeen, for which he paid £35, and to obtain which he states that he was, on the introduction of a certain Dr. Lang, examined by two Glasgow doctors of medicine deputed by the Aberdeen University, at the offices of Messrs. Lane and Lara, Medical Agents, in Adam Street Adelphi, London. The applicant produces evidence to show that he was apprenticed in 1830 by indentures, and states that he has been in practice ever since, but that severe illness has prevented him from passing any examination.

"*Resolved.*—'That a copy of Mr. Chappell's application, together with a copy of Dr. Lang's letter, and a facsimile of the diploma, be forwarded to the registrar of the University of Aberdeen, with a request that he will give the General Council such information as may enable the Council to decide on the case at its next meeting.'"

It will, no doubt, be interesting to peruse the explanation of the University of Aberdeen respecting this vicarious examination in a medical agency shop in London. For want of such explanation the matter certainly does not read well for the Scotch Universities.

The next business of the Executive Committee was to admit to recognition as a preliminary examination the matriculation test of the Michigan College of Medicine. This the Committee did upon the request of the President of the Medical Faculty of that College; and we do not doubt that they did rightly in so acting; but we avail ourselves of the occasion to point out that, if preliminary examinations about which the Council knows absolutely nothing are to be received into the list of examinations which qualify for a British diploma, there is really no reason why the same may not be done for American medical degrees of which the Council possesses the same amount of information. The Medical Reform Bills now before Parliament give the Medical Council absolute power to place the holder of any of these foreign degrees on an equality with the British licensee; and we are seriously apprehensive that, if these sections of the Bill become law, we shall have the *alumni* of the Eclectic College of Medicine and Surgery of Timbuctoo, or of some equally honoured institution, placed upon the Register, upon the faith of an *ex parte* statement from the officers of that College.

The dental business of the Council is, on this occasion, of extreme importance to those who practise this speciality. Our readers already know that by the Tomes-Lubbock Act a motley multitude of druggists' boys and self-dubbed dentists were admitted on their own declaration to the Dental Register as legally qualified dentists. The Association of Surgeons practising Dentistry now petitions for the "amendment or repeal" of the Act; and the British Dental Association petitions *contra*, but urges the expurgation from the Register of those names which have been improperly admitted thereto. At the same time the latter Association presents to the Council a list of persons who obtained registration as practitioners of dentistry "in conjunction with pharmacy," though—not being registered under the Pharmacy Act—they were really not at all—legally speaking—in the practice of pharmacy. The British Dental Association produces an eminent lawyer's opinion that these persons obtained dental registration by misrepresentation, and are, therefore, disqualified. It is now for the General Medical Council to take action on this representation; but the method by which the Executive Committee deals with it is ominous of a disposition to shirk responsibility, and keep at arm's length the complaining dental surgeons. The Executive Committee firstly calls for special facts with reference to each individual case, though it is obvious that no other fact is needed save the proof that the pharmaceutic dentist is not a pharmaceutist in law. Secondly, it allows a person who was detected in this misrepresentation to amend the entry after his name in the Register, and thus makes a precedent for allowing all others, under similar circumstances, to do the same.

We fear that the dental surgeons will yet have to seek solace from their lawyers and from the Court of Queen's Bench.

SUPERANNUATION FOR IRISH PRISON OFFICERS.

We learn that the General Prisons Board for Ireland has recognised the claim of the surgeon to the Carlow Gaol to a pension on the abolition of his office, the gaol being turned into a Bridewell. They have granted him £5 10s. a year on a previous salary of £40 and a comparatively short service.

Medico-Parliamentary.

HOUSE OF COMMONS.—Saturday, July 3rd.

ALLEGED POISONING AT WELBECK.

Mr. Mappin asked the Under Secretary of State for the

Home Department if his attention had been called to the alleged wholesale poisoning at Welbeck, Nottinghamshire, where several deaths had occurred, and it is said sixty persons have been ill; and if he would send a Government official to inquire into the whole affair, as the adjourned inquest had been held, and the deputy coroner expressed an opinion very much in opposition to the medical evidence produced.

Mr. PEEL observed that the Local Medical Officer of Health had been in communication with the Local Government Board on the subject. The inquest was now pending, and the medical officers were examining the intestines of some of the victims. If it was thought necessary to have an independent inquiry by the Local Government Board, no doubt that would be done.

Royal College of Physicians of London.—The following gentleman was admitted a Fellow of the College on July 2:—

Thomson, John Roberts, M.D. Edin., Bournemouth.

The following gentleman was admitted a Member on same date:—

Sarell, Richard, M.D. Edin., Pera, Constantinople.

Royal College of Surgeons of England.—The following candidates received the Diploma in Dental Surgery at a meeting of the Board of Examiners on the 24th of June:—

Richard Desmond Ashby, Richard Giles Bradshaw, Joseph Holland, William Robinson Humby, George W. Parkinson, M.R.C.S., Frederick Newland Pedley, Alfred Smith.

College of Physicians in Ireland.—Licences in Medicine and Midwifery were granted during the June examinations to the following candidates:—

MEDICINE.—Matthew Digan, George Digby, Isabella Margaret Foggo, Jane Russell Grant, Arthur Robert Harper, James Alfred Johnston, Henry Westenra Lentaigne, John Stephen McArdle, Sydney Pedler Morris, James O'Dwyer, Francis Alleyn Owgan, Henry J. C. Tweedy, Alice Vickery, John Warnock, Stewart Woodhouse.

MIDWIFERY.—Matthew Digan, George Digby, Isabella Margaret Foggo, Jane Russell Grant, Arthur Robert Harper, Hugh Harris, James Alfred Johnston, Henry Westenra Lentaigne, John Stephen McArdle, James O'Dwyer, Alice Vickery, John Warnock.

NOTICES TO CORRESPONDENTS.

THE INDEX.—The Index for the past half-year is unavoidably held over till next week, when it will be sent to readers with the regular number.

MR. J FLEMING.—If you consult a respectable practitioner in your town he will probably tell you there is little cause for anxiety if you ignore the instructions given you previously by the quack mentioned in your note.

THE SUPPLY OF PURE DRUGS AND VACCINE LYMPH.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Is it the intention of the Local Government Board ever to alter their requisitions and estimates for medicines in accordance with the present B.P., and if not, why not?—Will any dispensary medical officer who forwards pure vaccine lymph in tubes properly charged receive the sum of one shilling for each tube, or is this business entrusted to a special staff?

Answers to the above queries will oblige,

Yours faithfully,

June 25, 1880. A DISPENSARY HACK.

[1. Apparently the L.G.B. does not care a straw whether or not the paupers are poisoned or the ratepayers cheated. So far from taking any steps to put a stop to the scandalous frauds now perpetrated by drug contractors, we believe that the Board has tabooed in Parliament the propositions for reform suggested by the Irish Medical Association. 2. Only a selected staff of lymph-collectors is employed, but doubtless any competent vaccinator could get his name put on the list on showing cause.—ED.]

MR. C. C.—1. In September, 1879 2. About three years previously.

FEES FOR VACCINATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you be good enough to inform me, if a child is brought from a neighbouring dispensary district to my residence, can I legally charge the Board of Guardians the ordinary rate of two shillings for such vaccination? Of course I send the certificate duly filled up to the medical officer of the district in which it was registered.

I am, your obedient servant,

J. S.

[Certainly you must vaccinate any person, rich or poor, residing in or out of your district, and may charge the fee to the Guardians, but the operation must be done within your district.—ED.]

THE HARVEIAN ORATION.—Referring to this in our last issue we stated the orator to be Dr. W. Ogle (Censor of the College, and Consulting Physician to St. George's Hospital) instead of Dr. John W. Ogle. We also mentioned that Harvey demonstrated a capillary connection between arteries and veins in certain places. We are requested by Dr. Ogle to state that Harvey showed a connection between the vessels, but not a capiliary one.

NITRATE OF SILVER.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—What is the maximum quantity of nitrate of silver that may be given continuously without risk of skin discolouration, irrespective of whether administered in $\frac{1}{8}$ gr. or larger doses?

Yours, &c.,

F. C. F.

[Half-grain to grain doses of nitrate of silver may usually be given thrice daily for three or four weeks without incurring much risk of discolouration. If it does good in disease it is seldom needful to give it beyond a week or two. Most cases of discolouration arise from its protracted use in epileptics. In this class of persons we believe its effects are much over-rated.—ED.]

FOURPENCE PER HEAD.—Our friend Mr. Oliphant Betts, who was kind enough to bring an action for libel against us for expressing doubts upon his ability to give "medicine and advice at fourpence per head," has got into trouble with the Holborn Board of Guardians. An explanation having been requested concerning an inquest on the body of one Lucy Peddon, Mr. Betts vouchsafed to send a letter in reply, which the Guardians characterised as "monstrous, impudent, and disrespectful," unanimously deciding that it should be at once sent to the Local Government Board.

MR. H. CRIPPS LAWRENCE.—In an early number.

A FELLOW will see the result in another column.

RESIGNATION PRIOR TO APPLICATION FOR OTHER APPOINTMENTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Is a dispensary medical officer bound to resign the district which he represents before he enters as a candidate for another? What is the course to be pursued in such cases?

Yours, &c.,

KERRIESSIS.

[He is not bound to resign until he is about to leave the district, and he may seek office elsewhere as often as he pleases.—ED.]

VACANCIES.

Ardee Union, Collon Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Medical Officer of Health. Election, July 15.

Ballymahon Union, Ballymore Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, July 19.

Hertford General Infirmary.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Chairman before July 24.

Kent and Canterbury Hospital.—Assistant House Surgeon and Dispenser. Salary, £50, with board and residence. Applications to the Secretary, at Canterbury, before July 23.

Kilmacthomas Union, Kilmacthomas Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Sanitary Officer. Election, July 13.

North Staffordshire Infirmary.—House Physician. Salary commencing at £100, with board, &c Applications to the Secretary, Hartshill, Staffs, before July 27

Paris—Hertford British Hospital.—Resident Clinical Assistant. Salary, 100 francs per month, with board. Applications, with testimonials, to be addressed to the Physician at the Hospital, Neuilly, Paris, before July 20.

APPOINTMENTS.

BRANNEGAN, H. C., L.R.C.P.Ed., Assistant House Surgeon to the Liverpool Infirmary for Children.

BYASS, W. C., M.R.C.S.E., Medical Officer to the Dorchester District of the Wallingford Union.

CAITHNESS, J., M.D., C.M., Medical Officer and Medical Officer of Health for the Llanrhaiadr District of the Ruthin Union.

DICKINSON, T. V., L.R.C.P.L., M.R.C.S.E., House Physician to St. George's Hospital.

FISHBSON, F. J., M.B., C.M., Medical Officer to the Dalston District of the Carlisle Union.

FOX, F., M.R.C.S.E., L.R.C.P.E., Dental Surgeon to the Royal Hospital for Incurables, Putney.

JONES, W. D., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Llanfair District of the Ruthin Union.

MAIN, J. S., M.B., C.M., Assistant Medical Officer to the Workhouse of the Chorlton Union.

Births.

TEMPLE.—June 18, at Southsea, the wife of Surgeon-Major W. Temple, V.C., of a daughter.

Marriages.

HILLARY—FLOOD.—June 30, at the Pro-Cathedral, Dublin, Michael Hillary, L.R.C.S.I., to Myra, second daughter of Martin Flood, Esq., co. Galway.

Deaths.

BLATHWAYT.—June 30, at Lillington, Leamington, Wm. Blathwayt, M.D., F.R.C.S., aged 69.

COBCORAN.—Laurence W. Corcoran, M.B. Univ. Dub., Surgeon on board her Majesty's ship *Atalanta*, aged 26.

ELLIOTT.—June 30, at Bury Grange, Gosport, John Elliott, M.R.C.S.E., Deputy Inspector-General of Hospitals and Fleets, late of Corbo Clogher, co. Tyrone.

WALSH.—June 23, at Galway, Michael Walsh, M.D., aged 34.

Lectures

ON SOME OF THE

SURGICAL ASPECTS OF GOUT AND RHEUMATISM.

Delivered at the Royal College of Surgeons, June, 1880.

By Professor HUTCHINSON, F.R.C.S.,
Senior Surgeon to the London Hospital.

LECTURE IV.

MR. PRESIDENT AND GENTLEMEN,—In the last lecture we considered, as fully as the limited time at our disposal would permit, the various causes of gout and rheumatism; we have now to study the modes in which these diseases, having been once contracted, tend to become fixed—a part of the patient's "constitution"—and finally may be perpetuated in the race and form a diathesis. This tendency of the disease to persist and to pass on to graver forms is due in many cases to constitutional predisposition, but not always so; it may be due to local influences. The fact that a part which has once passed into a pathological state tends to persist in that course is well known to pathologists, and is generally spoken of as the *law of persistence*. Thus, suppose that a patient, with perhaps some slight constitutional tendency, gets rheumatic inflammation of a joint, then the continued use of that joint will keep up, and generally aggravate, the constitutional tendency. This joint may act as a sort of derivative to the rest of the body—the disease always attacks that part first, and the rest of the body escapes, or only a few other joints are affected; and when a single joint is thus affected the evidence of disease is generally highly developed. But in the majority of cases the tendency of the disease is to increase in severity and to spread to other joints.

Then since any influence which causes diminished tone in the system predisposes to an attack of rheumatism, one attack by thus lowering the tone will predispose to the persistence of the disease; and when once chronic disease is established it perpetuates itself and can only be thrown off by perfect rest and very careful treatment.

I have already said something about the influence of inheritance on these diseases, but should like to refer to this subject again, since I have based part of my theory concerning the nature of the arthritic diathesis on this.

If a patient inherits the arthritic diathesis, what is it that he takes? He takes all the proclivities which his father and mother possessed; they may relate to the nervous system, or to the digestive system, or to both. And the fact that he has inherited these proclivities may not show itself at once—the child may have to wait until the time of life at which certain organs begin to fail: the renal organs, for instance, may have always been somewhat weak, yet they fulfil their duties sufficiently well until slight degenerative changes commence, then inefficiency at once becomes evident and gout appears. In rheumatism, on the other hand, the inheritance is a peculiar state of the nervous system.

The fact that some of the family do not inherit at all, whilst others have a marked morbid inheritance is a stumbling block to many. We must remember that every child has two parents, and some children inherit from one parent, some from the other—this is known as the *law of prepotency*—so that if the morbid tendency is derived only from one parent, a portion of the offspring may be exempt. In some cases all the children in one generation may be exempt and yet the disease may re-appear in the next, an occurrence which is not uncommon in the case of gout, and which is known as the *law of atavism*. The patient Tretton, from whom that very characteristic knee-joint was taken, had three brothers and one sister all crippled with rheumatic gout, whilst another sister suffered from chronic rheumatism in a less severe form; in each of them the disease began early in life, and one would imagine that it must have been hereditary: yet I could get no evidence of any arthritic tendency in any other members of the family. This did not, however, negative the idea of heredity—it was probably a case of atavism, but their knowledge of their family did not go far enough back to supply the facts necessary to prove this.

I have already mentioned the hybrid diathesis, in which a patient has a tendency to suffer, not from pure rheumatism or pure gout, but from a mixture of the two; but I should like to explain this a little more fully, since it is a most important point in these lectures to prove the admixture. I hold, then, that Sir Benjamin Brodie and others were perfectly correct in their belief that these diseases might be combined in the same subject, and to such cases the term rheumatic gout is most properly applied. The patient may either inherit one disease and acquire the other, or they may both be derived from the parents. It is in this last case that we get the most marked hybridity. Suppose a man of rheumatic diathesis acquires gout by free living, he will suffer from attacks in which at on time rheumatism, and at another gout, predominates. But in the case of the patient who inherits the mixture you can't say of his symptoms which are rheumatic and which are gouty. He suffers, in fact, from peculiar maladies which can't be definitely referred either to one disease or the other, and the pathological anatomy is also peculiar. This explains the difficulty which has been met with in classifying cases of rheumatic gout.

About ten years ago, a florid, healthy-looking girl, æt. 18, came to me at the Moorfields Hospital suffering from a peculiar form of iritis leading to occlusion of the pupil; it had come on insidiously, and was apparently not severe, yet it obstinately resisted treatment; she had previously lost the sight of her other eye in the same way. Another peculiarity was that the ends of all her fingers were swollen and dusky. She suffered from pains in the joints on exposure to cold, but had never suffered from gout, and had no chalk stones anywhere. I performed iridectomy several times, and then had to remove the lens on account of opacity; after that the eye became quiet, but the girl became phthisical, and died about a year ago. For some years before her death all her joints grated, but she suffered little pain in them. Her father was gouty, and so were other members of his family, but this girl herself had no gout, nor did she suffer from any symptom which could be said to be clearly of a gouty nature.

Her case is not singular; I have met with several other examples of this peculiar form of iritis, and in all there was a family history of gout.

Does, then, pure gout undergo any change during hereditary descent, or are peculiarities of this sort due to the influence of the other parent? I should not like to say that it may not be modified by hereditary transmission, although it is said that in some well-known families gout has appeared in the same forms generation after generation. It is an interesting question, and one which I must leave for future investigators to decide. I have constantly noticed that the children of gouty parents are liable to certain special ailments long before they come to show their gouty inheritance; thus, they are very liable to sick headache, to neuralgia, to joint inflammation of a peculiar character, not affecting the great toe, but other joints, frequently the hip-joint. The child complains of great pain, there is a good deal of heat and swelling, and from the acuteness of the symptoms you would be inclined to give a grave prognosis; but after a little rest, &c., the symptoms all subside, and the child runs about again as before. These patients have also a remarkable tendency to hæmorrhages, to epistaxis, hæmorrhage into the vitreous, &c. I have now a patient, a stout, healthy-looking young man of 23, who has entirely lost the sight of one eye from hæmorrhages into the vitreous; he suffers also from headaches, epistaxis, and dyspepsia: he inherits gout. Retinitis hæmorrhagica, the form in which there are very numerous, flame-shaped hæmorrhages, is almost peculiar to gouty subjects.

Is there such a thing as gout without tophi? This is another interesting question which I have no time now to discuss. But if I may be allowed simply to state my own opinion I should say that I think there is; that there is such a thing as inflammation of a gouty nature, but not attended by deposit of urate of soda.

I need scarcely stop to point out that not only do gout and rheumatism intermix and modify one another, but either of them may intermix with and be modified by other diatheses; thus we meet with combinations of the gouty and catarrhal diatheses, and the gouty and lymphatic, general feebleness of circulation, tendency to chilblains, &c.

We have hitherto considered these arthritic diseases chiefly with reference to the way in which they affect the joints; we must now notice very briefly their effects on other organs of the body. And, first, we will take the iris, a structure which is most admirably situated for the observation of disease.

Arthritic iritis is very common in England, and has been very thoroughly discussed in English works. It is decidedly more common than the syphilitic form. There are several varieties; it is most commonly asymmetrical; appears first in early life and recurs periodically like gout, the attacks being most common in the spring. One gentleman came to me three years consecutively in the spring, suffering from iritis; he was a stout florid man, a large eater, and a beer-drinker, but not an immoderate one. He had rheumatic fever twice in early life, and from forty to sixty had frequent attacks of acute iritis. The attacks lasted two or three weeks, and then the inflammation disappeared; blisters and iodide of potassium were the only remedies which appeared to do any good. He suffered also from lumbago and sciatica, and when he came to me had had chronic rheumatic arthritis of the knee for years; still he was able to get about with but little inconvenience, and continued apparently in vigorous health until his death from cerebral hæmorrhage.

Less commonly arthritic iritis is symmetrical, and it is not unfrequently found in connection with general disorganisation of the joints.

I mentioned in my last lecture that gonorrhœa is a common cause of inflammation of the eye, and that the children of gouty parents are specially liable to this affection.

I have preferred to speak of arthritic, and not of gouty or rheumatic iritis, because according to my experience iritis is not common in those who are the subjects of pure rheumatism or of true gout, but is rather a sign of the hybrid diathesis. Out of 88 cases of iritis, 17 had gouty parents, and in 21 the patient had himself had some symptom of gout. In 16 it occurred in connection with gonorrhœal rheumatism, in 12 the patient was the subject of rheumatism, in 11 of crippling rheumatism (rheumatic gout), in 8 cases the patient had suffered from some slight form of arthritis, and in 3 cases only could no history of arthritis be obtained.

I have said that I do not consider iritis to be a common complication of pure rheumatism; when it does occur in this connection the inflammation is generally very slight; nor are ophthalmic disorders of any kind common in rheumatic subjects, though cases of conjunctivitis and sclerotitis, both slight, are occasionally met with. The diseases which occur in connection with true gout are retinitis hæmorrhagica, a few cases of recurrent iritis, and of opacities in the cornea. Sclerotitis punctata is met with in the children of the gouty, but is probably due to mixed inheritance, and the great bulk of the eye cases which are generally called rheumatic or gouty, occur in connection with this mixed diathesis, to which the term rheumatic gout may most correctly and properly be applied.

Then with regard to diseases of the skin. It is generally believed that eczema is a gouty affection, and that psoriasis is rheumatic. Dr. Garrod gives his assent to the truth of this opinion. This was one of the commonly received statements about which I felt doubts from the beginning, and which induced me to study the whole subject of arthritic diseases systematically. But even now my statistics do not enable me to answer the question decidedly; eczema especially is so common a disease that it is scarcely possible to connect it with any one cause or set of causes. I believe that eczema does occur in gouty subjects, but such cases are not sufficiently

common to justify the adoption of any routine treatment based on this idea. Each case must be treated on its own merits; if the eczema is found to be aggravated by indulgence in beer, &c., or by errors in diet, then it is probably gouty, and may be treated accordingly; but in the majority of cases some other cause will have to be sought for.

With regard to the connection of psoriasis with rheumatism, I believe the evidence to be still slighter; certainly I have not often been able to find any such connection. And I may add that I could not find that either eczema or psoriasis were exceptionally common amongst the patients under treatment at the Bath and Buxton Hospitals. Sciatica and lumbago are decidedly arthritic maladies. I must confess, however, that personally I find great difficulty in diagnosing sciatica accurately. At all events, I am decidedly of opinion that many of the cases which others diagnose as sciatica have nothing to do with the sciatic nerve. This is especially true of the very chronic cases in which the disease is almost invariably situated in the hip-joint—morbus coxæ senilis—though the pain is referred down the limb. Transitory attacks of pain are more often due to inflammation of the sheath of the sciatic. Lumbago, again, is properly an arthritic affection of the fascia attached to the large back muscles; but many of the patients who are said to be suffering from lumbago are really suffering from disease of the joints of the spine. As we see by the preparations before us, disease of these joints is common enough, probably as common as similar affections of the digits, &c., though it is comparatively rarely diagnosed during life. Both of these affections are more common in connection with the mixed disease (rheumatic gout) than with pure rheumatism or gout.

I have left myself but a very short time in which to speak of prevention and treatment; nor do I propose to say much on these heads. I have aimed rather at defining and classifying arthritic diseases according to their causes, since if we can find out the causes, the proper treatment follows as a matter of course. If rheumatism is due to reflex irritation of the nervous system by exposure of the skin to cold, then we must be careful to protect the skin and prevent this exposure. When, however, we have to deal with the mixed diseases the problem becomes a difficult one, and each case must be treated according to the indications afforded: thus, if the gouty symptoms predominate, the patient must be kept low; if the rheumatic, a more generous diet may be allowed, &c.

It may be said that I have deserted my proper field of investigation, and have been trespassing on medical domain; this may be so, but I do not consider it necessary to apologise. Surgery and medicine cannot now be divided by an abrupt line; the physician may indeed get on without much knowledge of surgery, but no surgeon with any sense of his own responsibility or of his duty to his patient, can feel satisfied without a tolerably thorough knowledge of medicine.

To recapitulate briefly—I hold that gout and rheumatism are two distinct diseases; each may be inherited, each acquired, each transmitted by inheritance, and may be modified in transmission. But I hold also that these diseases may be mixed, that they are in no way antagonistic, and that whilst many of the cases which have been *called* rheumatic gout are really cases of chronic rheumatism, many are really examples of this mixed form of disease. Rheumatic fever is the type of rheumatism, but the distinction between this and general destruction of joints is only one of degree, and the connection of one with the other can be traced through a series of intervening links. I may have appeared to have dethroned gout from the prominent position usually given to it, but I believe that whilst cases of true rheumatism are tolerably common, cases of true gout are not common; most of the cases which are called gout would be more correctly described as rheumatic gout. Sir Benjamin Brodie and others have advanced these opinions before me. I have brought forward very little that is really novel, and I have on that account the more confidence in the results to which my own independent investigations and reasoning have brought me. Lastly, if some of these conclusions have placed me in apparent opposition to some who have devoted themselves exclusively to the study of this subject, I would remark that it is a great advantage to be able to gather one's materials from a wide field, and that it is possible for a specialist to stand too close to his subject, and thus to fail to take in correctly all its relations.

Original Communications.

SUGGESTIONS RESPECTING A MEDICAL AND SURGICAL BED-DRESS.

By H. CRIPPS LAWRENCE, L.R.C.P. Lond., &c.,
Physician to the North West London Dispensary.

The requirements of medical and surgical practice often necessitate the change of body-clothes under circumstances which render it all important that the patient should be moved or disturbed as little as possible. It may be necessary to avoid fatigue, alteration of posture, or some allied condition; and in such cases the form of bed-dress suggested may prove of service. The idea has been carried out by Mr. Goode, of 50 Praed Street, Paddington, and he has in stock samples for inspection.

The original principle suggested by me was to substitute buttons along the front and back and down the seams of the sleeves, in lieu of the usual plan of placing buttons at the top in front, and at the wrist-bands only. By the above method, the dress or any part of it can be readily opened for purposes of inspection, auscultation, the application of poultices, remedies, &c., without disturbing or raising the patient. If need be, the dress can be practically divided into two halves for removal or re-application with the least possible difficulty. Various modifications of the ordinary long-cloth material can be employed; such as long-cloth lined with flannel, or flannel substituted for the long-cloth; or any part can be lined with macintosh to meet the requirements of medical or surgical practice. Mr. Goode is prepared to apply such alterations as any individual practitioner may wish to the original principle.

Should bed-sores threaten, the buttons can be altered and placed at the sides instead of at the front and back; or if preferred, removed altogether, and tapes or elastic substituted.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY, F.R.C.S.I., M.B.

(*Continued from page 540, last vol.*)

Amputation of Breast (Two Cases). (a).

A. Married, but without family, æt. 40, a delicate woman, and the subject of chronic bronchitis. Catamenia regular; tumour of small size at upper end; outer part of the right breast a year growing, and slightly adherent to both skin and pectoral muscle. Removal was effected by elliptical incision; the affected portions of skin, and some fibres of the great pectoral being freely taken away. After bleeding was staunched the wound surface was dabbed into a 40-grain solution of chloride of zinc, and dressed into due provision for drainage from both angles. Subsequent to the operation some distress was caused by cough, but the progress of the wound, though slow, was favourable. On the 9th day patient was able to get up and begin to go about. In four weeks all was healthily healed.

B. Subsequent Sudden Death.—Patient, æt. 60, also married, without family, and a subject of chronic bronchitis, naturally a feeble, delicate woman, whose present condition was depressed below par in consequence of a recent attack of diarrhœa. The tumour was in the left breast as big as an orange; axillary glands moderately implicated. The patient was very urgent for immediate operation, and, with difficulty, was got to acquiesce in a few days' preliminary treatment, during which the general state improved considerably. After the removal of the tumour and arrest of any bleeding points, the outer angle of the wound was prolonged, and one large, together with several smaller glands, were readily taken away. Altogether there was not one ounce of blood lost; three vessels were secured with carbolised catgut. The subsequent dressings were as in the preceding case. After operation patient rested nicely, slept well, passed urine freely, and seemed in every way to be doing promisingly. When seen at midnight she appeared to be in right good form. Two hours later a severe "shivering fit" suddenly occurred; the woman at once became cold and collapsed, from which state she could not be roused, and died twenty-nine hours after the operation. There had been no hæmorrhage whatever. No autopsy permitted.

Obscure Tumour of Groin—Recurrent Malignant Disease near Axilla.—A woman, said to be 50 years of age, but really several years older, whose right breast had been removed 3 years previously, came under observation with a recurrence of the malignant trouble, and a tumour in the right groin; this latter was as big as an orange. According to the patient's account, it appeared three weeks previously, growing downwards, and steadily enlarging, till it was "put back" by a surgeon a week before admission. The reduction was described as complete, and readily effected by the taxis. Three days later on the tumour again appeared. It, in shape, size, and position, gave one, in a general way, the idea of a large femoral hernia, mainly containing omentum, rather soft in places, and receiving, in a doubtful way, a vague impulse on coughing: an ill-defined prolongation could be dubiously traced to the femoral canal. In certain positions, just a suspicion of fluctuation could be detected. There was no tympany. Taxis, or the application of continuous pressure by shot-bags, obtained a manifest reduction in size. There was history of obstinate constipation and vomiting. Such were present on admission, but were speedily subdued, and the bowels acted freely. The pulse-rate was 70; no local tenderness or pain; urine normal in gravity and composition. The other tumour, as big as a large-sized walnut, was placed on the edge of the anterior fold of the right axilla; a small portion of skin was intimately adherent, and sunk into it, there were also some adhesions to the pectoral. No deeper gland contamination could be ascertained. Removal was easily effected by two elliptical cuts; behind under cover of the growth two small glands found embedded, were excised. The wound surface, after being dabbed with the usual solution of chloride of zinc, was brought together with a few parts of carbolised catgut suture, due provision being made for drainage. On the second day after the operation an unusual discharge of slightly reddish fluid was observed, but, otherwise, the woman seemed in every way to be doing excellently. Two days later, this fluid having increased in quantity, and being redder in colour, the surface adhesions were torn through, and some clots turned out; there had been no deep repair. The wound was now dressed from the bottom, and daily improved in appearance. At midnight of the eighth day, there was a severe rigor, and the next morning the woman looked badly. The subsequent midnight the rigor recurred, but was not so severe. At 2 o'clock on the afternoon of the tenth day, there was a sudden and severe dash of bleeding; this was promptly arrested by plugging the wound with stypticised pledgets. These were removed after a couple of hours, in consequence of very slight leakage, which then ceased, and the source of the bleeding could not be made off by the most thorough search. The whole cavity was carefully and firmly packed from the bottom, but ten hours after the preceding bleeding, now again at midnight another profuse spurt took place, and death occurred immediately.

A hastily made and partial autopsy, which alone could be secured, showed the groin tumour to be a very thick-walled purulent cyst (*a*) communicating with the pelvis beneath Poupart's ligament externally by a narrow neck; a sinuous prolongation traversed the iliacus muscle; and the psoas extending to the shoulder of the sacrum, but beyond a very small superficial, purely surface erosion, no bone trouble could be made off.

(*To be continued.*)

(*a*) Scirrhus in both.

Department of Lunacy.

THE SOUTH YORKSHIRE ASYLUM.

The statement made by Dr. Mitchell in his annual report on the South Yorkshire Asylum, that insanity is emphatically a preventible disease, and that it overtakes its victims only amongst those who viciously or ignorantly disregard the most simple laws of healthy and sober living, can only receive a very qualified assent. It is often a disease, which no precautions could have prevented, at least, no precautions which it was in the power of the individual to take, the seeds of it having been sown in bygone generations, and its shoots nurtured by successive prognitors. Then how can a man prevent the concussion of his brain in a railway accident which results in his mental disorganisation; or the typhoid fever which leaves him a helpless imbecile, and which was incurred by drinking the only water to which he had access? In a wide sense—so wide as to have no meaning—it is correct to say that insanity only attacks those who have disregarded the laws of which a number are as yet undiscovered and unsurmised. Obedience to what Dr. Mitchell calls the simple laws of healthy and sober living will certainly not suffice, else why should the Quakers suffer from insanity even in larger proportion than other men? There seems reason to believe that an excess of sober living may be itself a cause of insanity, and that the brain that is never stimulated becomes soddened into uselessness and fatuity. The fact is that simple theories as to the etiology of mental diseases will not hold water. The question is an eminently complex one.

(*a*) Illustrative of the possible simulation of hernial protrusion by certain purulent cysts, another example happened, by coincidence, to be also under observation at the hospital about the same time, in the person of an under-middle-aged married woman, in whom an easily reducible tumour, receiving impulse on coughing, had gradually formed; it came down beneath Poupart's ligament, external to the vessels. The patient long wore a truss. Subsequently a similar protrusion formed on the left side. Eventually the diagnosis of double psoas abscess was proved by the autopsy.

THE BRISTOL CITY AND COUNTY ASYLUM.

THIS asylum which contains upwards of 200 patients is under the superintendence of Dr. George Thompson, who mentions in his annual report which has just reached us, that nearly one-half of the patients admitted have been sent from workhouses, where they had been detained for some time before being forwarded to the asylum to the jeopardising of their prospects of recovery by depriving them of skilled treatment at the very time when it would be most efficacious.

IMPORTANT LUNACY CASE.

ON Friday last a case of illegal reception of lunatics. in which the Treasury prosecuted, came before Mr. Flowers, at the Bow Street Police Court.

Mr. Poland, in opening the case on behalf of the Treasury, said this was a case of great importance. The defendant, Mrs. Rutley, of 12 Northlands, Wandsworth, was in the habit of receiving as patients a number of ladies, who resided there for the purpose of being treated as lunatics. Information was given to the Commissioners in Lunacy, and in consequence, it was thought right to obtain an order from the Lord Chancellor authorising a medical gentleman to visit the defendant's house. Accordingly, Dr. Blandford was directed to pay the establishment a visit. He did so on the 20th April, and found nine ladies living in the house. He had interviews with them, and amongst this number there were two who in his opinion were of unsound mind. With regard to the other patients it was not necessary to enter into the details of their cases, but some of the patients made complaints. Finding the facts were to be disputed, another physician of high standing was directed to see the patients, and he entirely concurred in the opinion given by Dr. Blandford.

Dr. G. Fielding Blandford said he visited the houses 10 and 12 Northlands, Wandsworth. He saw Mrs. Rutley, and explained to her he had come from the Commissioners in Lunacy to see the inmates of her house. She gave him all the information he asked for about them, and he afterwards saw them one at a time. He paid a second visit, accompanied by Dr. Risdon Bennett. In his opinion, two of these ladies were certainly of unsound mind. He formed the opinion on his first visit, and it was confirmed on his second.

Dr. Risdon Bennett. President of the Royal College of Physicians, deposed that he went to the defendant's house in company with the last witness, and believed the first patient mentioned to be in a chronic state of lunacy. The second patient was an absolute imbecile, and the third was a person of weak mind, and if in lodgings and alone she would be quite incapable of taking care of herself.

Formal evidence was given to show that the defendant had not taken out a licence, and on an intimation from Mr. Flowers that it was a case he could not withhold from a jury, defendant's counsel elected to reserve his defence.

The defendant was committed for trial on the first summons, and the hearing of the second summons was adjourned.

ANNUAL MEETING OF THE GENERAL MEDICAL COUNCIL.

WEDNESDAY, JULY 7.—THIRTIETH SESSION.

Dr. ACLAND, M.D., F.R.S., President, in the Chair.

AFTER the formal introduction of Dr. THOS. BANKS, as representative of the Queen's University in Ireland, by Dr. HAUGHTON, F.R.S.,

The PRESIDENT delivered an address, of which the following is a *résumé*.

THE PRESIDENT'S ADDRESS.

The pressure of educational questions which await your decision has made it necessary to summon the Council to this its 30th Session. Several important documents having reference both to the general and to the professional education of the medical student, demand the attention of the Council. It is unnecessary for me to speak of them at length, so that I will only relate briefly what they are, and in what form they will come before you. The President here detailed the resolutions arrived at in 1877 with regard to general education, the answers thereto of the licensing bodies, and the work of the Council thereon. He then said :—Upon these documents, which have already been unofficially circulated for the convenience of the Council, several notices of motion have been framed. More than one of these notices directly open up the question on which so much discussion has been raised of late years, of what are the subjects which should be included in preliminary examinations, and, therefore, what should be taught in the schools—as, for instance, physics, geology, zoology, and other subjects. And the further and really more important question is asked—how they are taught, and what is the standard of examination? The Executive Committee reports concerning seventy-two examining boards which the Council recognises as giving certificates of proficiency in general education, that they satisfy "the requirements of the Council with great uniformity." They conform, that is to say, with respect to the subjects of examination, but how far they are uniform in respect to the answers which may be expected, the Committee have, at present, no means of judging. It will be observed that members of the Council are of opinion that notwithstanding the great progress which is known to have been made in the means of educating students, and partly in consequence of it, the extent and quality of the general education given to them needs re-consideration. It will be proposed, therefore, by Dr. Storrar, that the whole subject be referred to a Committee. Meanwhile, it may be well to observe at once, in favour of this course, that since the time when Council first laid down the general arrangements which it would recommend in respect both of general education and examination, not only has the subject of general education, as conducted in the higher schools, been reported upon by three Royal Commissions—viz., by Lord Clarendon's, in 1864, Lord Taunton's, in 1868, and the Duke of Devonshire's, in 1874—but that, without doubt, great improvements have taken place in secondary schools, and in the school books which are used in them. But still questions of great difficulty remained unanswered ; for instance, it is still a matter of debate in the old Universities whether Greek shall be a compulsory subject for the Bachelor of Arts degree, and whether those who have degrees in natural science shall have had the same general education as other graduates. And it must be admitted that scientific men are by no means agreed on these points. When this Council has reconsidered its own requirements the schools will, without doubt, know how to meet them. Meanwhile, motions will be brought before you, both by Professor Haughton and Dr. Leet, to the effect that Greek be made compulsory on all medical students, so that the amount and character of linguistic studies and examinations, as well as the extent of scientific subjects, proposed for students prior to their professional studies, is again raised. The subject of professional studies and examinations will again be specifically brought before the Council. Memorials were laid before you last year suggesting that certain special modes of study should be made compulsory in respect of ophthalmology and gynæcology. You directed that the memorials should be forwarded to all the licensing bodies for their observations. The report from the several bodies will be laid before you, with a report thereon from a committee specially appointed by the Council, consisting of Dr. Humphry, Dr. Andrew Wood, Dr. Aquilla Smith, Mr. Simon, and Mr. Teale. A further communication of a similar kind on the subject of mental diseases, forwarded on August 4, 1879, from the Medico-Psychological Association, will be laid before you. The question will thus be re-opened whether it is possible with advantage to the solid acquirements of the student to add more details to those already required in the four years of professional study—or whether more years are, as in some other countries, to be demanded. It remains only as my privilege to add that which the Council will be pleased to hear, that no discussions on Parliamentary Bills need this year distract them from their appointed and congenial work of superintending the studies and examinations that bear on the profession of medicine, and of conferring with the great institutions of the nation that undertake the duty of conducting them. Last year there were three Bills before Parliament dealing with these and other subjects. The Government had thought it well to refer these Bills to a Committee of the House of Commons for report, as a means of affording to those who desire to support any particular views on them to express

their opinions. The Committee were unable to report either last year or this year before the dissolution of Parliament. No Bills of this kind are at present in either House, and the Committee is accordingly not re-appointed. On the 27th of May the Vice-President of the Privy Council, in reply to a question put to him, stated that during the coming recess the whole question would be considered by the Government. Meanwhile the Council are steadily pursuing the work which Parliament assigned to them, and on which they have been so long engaged. This increases every year in interest and importance. It increases in interest with the rapid advance of purely scientific biological knowledge, and its relations to the prevention and the treatment of disease. It increases in importance because this very progress—this mass of daily advancing knowledge—makes us all feel the accumulated force of the pregnant words of our old Greek master, Πεῖρα σφαλερὴ κρίσις χαλεπή. They only who take a superficial view of the present condition of the science and of the practice of medicine think it a light task to say what portions of each are necessary for our younger students—how they should be taught, and how tested. Probably there is no medical institution that is not ready to say that in these days it has learnt much—perhaps not one will aver it has not something yet to learn. We, too, whether sent for common deliberation by a university or corporation, or by the Crown, feel each year the benefit and necessity of that interchange of thought for the common work of our profession and of the nation, of which a responsible body like this Council is the centre.

The following Committees were then appointed :—

Business : Drs. Andrew Wood, Aquilla Smith, Leet, Haldane, and Pyle.

Finance : Drs. Quain, Pitman, A. Smith, and Scott Orr.

MENTAL MEDICINE.

A petition was read from the Medico-Psychological Association, asking that the Council would recommend mental diseases to be included as a subject of examination for all degrees and licences to practise medicine in the United Kingdom.

Dr. QUAIN thought the Council ought not to assent to the proposition, but moved that it be entered on the minutes, in which he was supported by Professor Turner, and the Rev. Dr. Haughton expressed an opinion that this petition and those presented in respect to ophthalmology and midwifery rested on entirely different bases.

Sir WILLIAM GULL did not think the Council should advise the course suggested in the petition. *Material* diseases first demanded study, and ought not to be cramped in favour of specialties during the regular curriculum. The treatment of mental affections forms part of the subject of practical medicine, and it would be absurd to teach it on any other supposition. There is no criterion of a good intellect, and the subject under discussion was, he contended, taught generally, as far as it is known ; students do go to asylums, but all cannot be expected to spend a large portion of their time there observing the phases of insanity.

Dr. AQUILLA SMITH and Mr. MACNAMARA were followed by Rev. Dr. Haughton, who explained that ophthalmology and midwifery were subjects in which the licensing bodies required candidates to be read, but the case with mental medicine was different. Let the psychologists themselves make application to the examining boards, and when a majority of the seventeen corporations assent to their demand, then let the test be a general one. The motion as it stood was an implied censure.

Dr. PITMAN pointed out that the memorial of the obstetricians was forwarded for report to the licensing bodies, an action not pursued in the present instance.

Dr. ANDREW WOOD insisted that the Council could not call on the licensing bodies to examine in so great a subject. The four years' course of study would not admit the subject being adequately pursued, and the proper time to study mental disease is after qualification. He thought the best answer to return would be that the Council did not deem it expedient to suggest that the subject be included in the scope of examination by all licensing bodies, and moved an amendment to that effect.

Dr. BANKS (who had been previously introduced as the representative of the Queen's University in Ireland, in succession to Sir Dominic Corrigan, deceased) said the Queen's University was not prepared to recognise mental diseases as a subject of particular examination unless the curriculum was extended.

Mr. TEALE considered the Council ought to determine how great knowledge of the subject can be demanded from men who might possibly not follow it out, and how best the acquirements of specialists could be utilised.

Prof. ROLLESTON imagined the facilities for early treatment of mental cases were such as to obviate any necessity for general practitioners to make it a special branch of study. It was otherwise with obstetrics.

Mr. SIMON said the objection was to making the subject *special*. At the College of Physicians candidates are liable to be questioned on mental diseases, and he hoped some knowledge concerning them was common to general practitioners.

Dr. HUMPHRY and Mr. TURNER having spoken in terms reflecting the general impression, the amendment to the motion was eventually carried, as a substantive motion, to the effect that the communication be acknowledged, but that action be not taken on it.

RETURNS FROM THE ARMY MEDICAL DEPARTMENT.

Dr. HUMPHRY moved that the returns of degrees, licences, and diplomas of candidates for commissions in the medical department of the army be entered on the minutes, and that the best thanks of the Council be expressed for them. He commented on the improved state of preparation of candidates as shown by the number of rejections now and formerly.

Rev. Dr. HAUGHTON took exception to the rosy picture drawn by Dr. Humphry. The period preceding the new army warrant was a low tide one with the Army Medical Department, and the examination standard was lowered.

Sir JAS. PAGET felt certain the army medical examinations have steadily progressed.

Mr. SIMON and Dr. HALDANE having spoken to it, the motion was carried.

A negative reply was returned to Dr. STORRAR'S inquiry whether like returns had been made from the Navy and Indian Service Departments.

With some slight alterations a table showing the results of professional examinations for degrees, diplomas, and licences granted in 1879 was agreed to be entered on the minutes.

Tabular returns from examining bodies, showing how far their regulations and practice in regard to the seventy-two examinations at present recognised by the General Medical Council are such as to satisfy the Council's requirements in regard to preliminary education, were, on the motion of Dr. Humphry, seconded by Dr. Andrew Wood, directed to be entered on the minutes. A similar course was adopted with regard to a report from the Executive Committee, to the effect that, "in accordance with the desire of the Branch Council for England, expressed in its resolution of January 29th, 1880, they have obtained detailed information respecting the nature and scope of each of the prelinary examinations recognised by the Council. This information, analysed and tabulated, is presented to the Council. The Committee call attention to the fact that one of the results of the information obtained is to show that the regulations of the several examining bodies are generally in accordance with the recommendations of the Council."

Several communications from the Branch Councils on the subject of preliminary education of medical students, embodying the opinion of most of the licensing bodies, were resolved to be entered in the minutes of the Council, on the motion of Dr. A. Wood, seconded by Prof. Humphry.

A communication from the Royal College of Surgeons of Ireland, dealing with the preliminary education and examination of medical students, having been read, and its incorporation in the minutes moved by Dr. Wood, Mr.

Simon, in seconding the motion, asked for an explanation of the passage in which the Secretary to the College writes, "I am directed by the Council to express their regret that the General Medical Council does not take similar strict action with regard to such other medical authorities as are not acting in accordance with the recommendations of the General Medical Council."

Mr. MACNAMARA said the R.C.S.I. knew that when the letter was written to it, demanding that they should require all candidates for licence to pass a prel iminary general examination, other bodies were guilty of the irregularity charged to them, and they felt it hard to be specially taxed with wrong doing.

Rev. Dr. HAUGHTON having spoken to the motion, it was carried.

PRELIMINARY EDUCATION.

Dr. STORRAR moved :—"To bring under the consideration of the General Council the Reports of the Branch Councils on the answers from the medical licensing bodies, in regard to the preliminary education of medical students, and to move—That the recommendations of the General Council for preliminary education and examination be referred to a Committee, to consider and report as soon as possible whether any, and, if any, what changes may with advantage be made in them." Since the General Council last met, said Dr. Storrar, great changes had occurred. A fresh Government had other questions to engage its attention than that of medical reform, and we hear nothing of legislation, immediate or remote. The efforts of the General Medical Council to consolidate examinations should, however, be continued, and its persuasion used to influence public opinion towards moving the various bodies. These efforts continued would eventually force Government into action. He would, however, at present, confine himself to a statement of the position in which the question of preliminary education stood. He was one of the oldest members of the Council which, in 1859, on his motion, appointed a committee on medical education. That time was the golden period of the question, when a strong feeling was prevalent that defective preliminary training was to blame for the inefficient state of the medical profession. It was apprehended (1) that there were some subjects essential to be known before entering on a medical curriculum, and (2) that a definite *mental* discipline was likewise a necessity towards fitting men to practise medicine. Considerations of the kind led to a desire for a common general education of the candidates for professional qualifications.

Dr. Storrar then went into a lengthy review of the resolutions adopted from time to time, and of the origin of the Arts examinations, instituted by the licensing bodies. He sketched the history of the subject for the past twenty years, and especially drew attention to the omission by the Council of its requirements, that the preliminary examination should be conducted by a board of examiners qualified in arts, dating deterioration from laxity in this particular. Frequent attempts, he showed, had been made to preserve the integrity of the Arts examination by Arts examiners, but ineffectually. He accused the Royal College of Surgeons of England of impropriety in retaining the College of Preceptors to conduct its Art examinations, while, at the same time, withholding the actual determination of standard and efficiency to itself. This could but tend to a reduced standard. Durham alone of the Universities insists on a special examination in Arts from its medical students, but the state of this examination revealed on inspection was shameful. Of 951 students registered in 1879 only 240 passed a preliminary test he, Dr. Storrar, deemed sufficient. In Scotland and Ireland the results were still more deplorable. The number corresponding in Scotland was only 27. Moreover, a large number of the young men examined are tested by bodies interested in their success, and the absolute rivalry existing among different corporations intensified the evil.

Dr. Storrar severely criticised the "remanet" system of examination, denominating it as a pestilential encouragement to cram. It was impossible, he urged, for anyone in England to contemplate the Scotch system and not deem it radically wrong. The Queen's University of Ireland even permitted students in 1869 to enter on medical study without a previous Arts examination. Contrasting the present state of medical education with what the Council contemplated in 1859, he admitted some good had resulted, but much more remained to be done. If legislation affords no help to correct the competition of licensing boards, an attempt should be made by representing the evil to them. Dr. Storrar concluded by expressing a wish to see a scientific examination introduced between the preliminary and first professional tests.

Sir WM. GULL seconded the motion, but did not agree with the mover on one point. There ought to be a certainty that men entering the profession *have* minds to be trained; and he would insist on an *intellectual* test over and above a mere preliminary examination. By raising the status of the profession a better class would be secured to enter it. A proper scheme would provide more time for actual medical study, and Sir William considered the Universities would do wisely to take more especially the general training of students, and leave technical instruction to hospitals.

Mr. MACNAMARA believed time would be saved by immediate discussion of the whole matter by the Council; it must some time be decided so once for all. A Commission could not deal satisfactorily with it. He thought the Colonial bodies which had forwarded no returns should be struck off the list of qualifying bodies, and similarly with all examining boards of which the Council had not accurate information as to standards, &c. He corrected Dr. Storrar's statement concerning the Royal College of Surgeons of Ireland, which, he said, never during its existence had given a licence without demanding a proof of preliminary education.

Dr. STORRAR explained that a preliminary examination meant one passed before commencing medical studies, and not, as Mr. Macnamara implied, one passed some time before qualifying in medicine or surgery.

Rev. Dr. HAUGHTON thought no sufficient reason for appointing a committee existed. Dr. Fergus had embodied the principle of the motion in a resolution to be taken later, and he thought it undesirable the Council should shelve its responsibility on to a committee. The University of Dublin recognised only one (its own) preliminary examination, and on the list printed there were no less than seventy-two recognised by the Council. He read a letter recently addressed to him by an intending medical student, requesting information as to the preliminary examination, and offering to *purchase a testamur* of having passed it. He inferred this would not have been written without cause, and that somewhere the practice of purchasing a pass was not unknown.

Mr. TEALE and the President having spoken,

Dr. BANKS moved the adjournment of the debate, which, being seconded by Mr. Macnamara, was carried *nem. con.*

Certain minor motions referring to unimportant points being submitted and carried, the Council adjourned.

SECOND DAY.

The report of the Committee on Ophthalmology and Midwifery having been read, and its adoption moved by Dr. HUMPHRY,

The REV. DR. HAUGHTON objected to placing the two subjects on a level of importance, and moved an amendment to the effect that midwifery be separated from ophthalmology, and that the latter be treated in accordance with the resolution.

Dr. WOOD suggested the motion should remain over till after the conclusion of the debate on preliminary education.

This was accepted.

PRELIMINARY EDUCATION.

Dr. BANKS said he should be disloyal to the body he represented did he not repel Dr. Storrar's charge against it. The Queen's University in Ireland had always responded to the Council's recommendations, and had in nothing lowered the standard of preliminary examination. Every subject named by the Council was included in the matriculation test of Queen's University, and even more than was required, Greek being a compulsory subject. The unsatisfactory report of the visitors who commented on the University's examinations, called forth a protest from the examining board, the members of which declared no proper investigation had been made, and challenged the General Medical Council to send its own commission of inquiry. Dr. Banks felt convinced that Queen's University deserved high credit for its exalted examination standard, but it had much to contend against in the deficiencies of the schools. The regulations as to intermediate education would, however, he hoped, remedy the defect in the future. Dr. Storrar seemed to forget that in 1879 most favourable reports were made as to the medical examinations conducted by the University, and Prof. Humphry thought so highly of the anatomical examinations that those held at Cambridge had been modelled on them. Though the general examination was incorporated with the technical, it suffered no diminution in severity thereby. Dr. Banks would like every medical graduate to be a graduate in Arts also. As visitor of the Queen's University, and as examiner in medicine at it also, he had been favourably impressed with what he had seen there.

Dr. PETTIGREW complained that Dr. Storrar had reflected unfairly on those Scotch corporations in which he said that examinations properly conducted would reduce the number of students resorting to them.

Dr. BANKS added that at the Queen's University the examinations were so severe, the men often would not face the test they must pass to graduate in medicine.

Dr. SCOTT ORR said Dr. Storrar had unfairly quoted a number of disjointed passages as to Glasgow University, which, when so presented, were calculated to give improper views of the system there in vogue. Extramural schools were, he contended, wholesome rivals to Universities, and in proof that strictness was observed in respect to preliminary training, he would mention that elementary mechanics had been lately made a compulsory subject at Glasgow. The medical faculty of the University considered that a thorough and efficient inspection of examinations is necessary.

Dr. PYLE averred that Durham University had loyally adopted all the recommendations of the Council. When it advised a special examination for medical students the suggestion was carried out, and there was no doubt that future recommendations would be as carefully attended to. Unlike London University, Durham was an educational as well as an examining centre, and the necessity of residence on the part of the candidate for its degrees reduced the number who proceeded to them. The Arts standard of Durham was as high as that of Oxford or Cambridge, and the examinations were in part conducted by Arts examiners from the more ancient universities.

Dr. STORRAR inquired if residence was required from *medical* students?

Dr. PYLE explained that special examinations were held for candidates for medical degrees, who were required, instead of actually graduating in arts, to show a knowledge of the subjects required for it, half as much as the candidate in Arts alone must exhibit.

Prof. ROLLESTON thought Glasgow should be thanked for pointing out the temptation to corporations to sail near the wind. University examinations of extramural schools must react injuriously on the latter; and an impartial examining board in general education could alone act as a check to a possible improper use of authority. The conjoint scheme, obstructed by the action of the Scotch corporations, would have obviated the serious dangers that exist from this cause now.

Prof. TURNER regretted the discussion had fallen on so many side issues. Dr. Storrar's speech had been condemnatory, historical, and apologetic, but the historical *résumé* would not be likely to influence the vote of the Council. That degeneration from an age of gold to one of lead had occurred seemingly proved the inutility of the Council's proceedings, and the next stage may be that of pinchbeck. The condemnation of Dr. Storrar reminded him of the Commination Service. The English and Irish bodies had uttered their defence, and he, speaking for Scotland, could say Dr. Storrar was inaccurately informed as to the system of preliminary medical education in that country. He felt that for a member of the General Medical Council to imply improper action on the part of a Scotch examining board was reprehensible. In Edinburgh the preliminary examinations were held before those in science and medicine, but in the faculty of arts no preliminary examination was enforced. Such a test would, however, be introduced next winter. The preliminary examination of medical students was conducted by examiners in Arts, in precise conformity with a former resolution of Dr. Storrar's, seconded by Dr. Rolleston. This was true also of Glasgow and Aberdeen. At Edinburgh the papers were set by gentlemen specially appointed for the purpose, and who have no connection with the medical faculty. They are subsequently submitted to the faculty of arts, but the medical examiners have no connection with them, the only professional officer of the University associated at any time with the testing of candidates at the preliminary examination being the dean of the faculty, who presides, after the examination, during the recording of the results. The rejections are considerably over 33 per cent. The "remanet" question had been unduly denounced by Dr. Storrar. He (Dr. Turner) thought it would be exceedingly unfair to candidates possessing testamurs from Oxford, Cambridge, or London, to require that they should undergo examination afresh in all the subjects they had already passed. This was avoided by permitting them to take up only such additional matter as proved an essential part of the Edinburgh examination, and which had not been part of that they had already passed. For instance, Greek and logic not being essential to a London University candidate, these subjects must be taken up by a matriculated student of London who seeks an Edinburgh M.D. Dr. Turner thought the medical student himself is too little considered in these discussions on his training. It would unduly hamper a student to refuse any preliminary certificate except that issued by the special licensing body he applied to. Such a proceeding might seriously hinder his progress. Four courses were possible with respect to the subject of debate. It might be reported on next year or next Saturday, or considered by the whole Council in committee, or discussed by the Council in open session. He thought the Council might settle the matter without any committee's report. The time had come for this to be done. The standard of preliminary education might be raised, and experience proved that the preparation of students would keep pace with it. It should not be raised too high, however, because of the number of licensing bodies who would be affected by it. Dr. Turner concluded his speech by remarking on the success achieved by the Edinburgh local examination scheme, which drew to it 800 to 900 candidates yearly, and which possessed centres even in England.

Mr. SIMON considered the discussion on the motion ought to follow that on the previous reports, several of which from branch councils were in hand. It would be ridiculous to repeat discussion on the same points again and again. The best attention of the Council should be given to establishing a system of preliminary education after reviewing all former resolutions, but he feared little weight would attach to any recommendations of the Council now, in consequence of its present uncertain position, and while it was so situate it would receive little attention. Pending a decision on the points raised against the Council before the Parliamentary Select

Committee it would be a waste of time for it to make resolutions. Three corporations had already refused to pay heed to the Council's demands, and its influence was growing less. He was prepared to vote that the examinations complained of be no longer received as sufficient to satisfy the Council's requirements, and he counselled an urgent application to Government to terminate the unsatisfactory position of the Council.

Dr. A. Wood deplored Mr. Simon's speech, which sought to make the Council abdicate its functions. Agitation for reform of the Council, Dr. Wood said, had produced the obstruction to progress they had witnessed in the past. He agreed, however, that it would be futile to refer the question under debate to a committee, but in opposition to Mr. Simon he contended that the Council had done immense benefit by securing some uniformity of examination, and that a preliminary test should precede registration as a medical student. Licensing bodies, moreover, with a few exceptions, had been ready to adopt the Council's recommendations, and Mr. Simon's strictures and suggestions it were impertinent to follow. If they waited a Governmental settlement of their position they might wait the advent of the Greek Kalends. The Council should accept the present as a breathing time, and afford an example of action to the licensing bodies. Dilatoriness now would hinder future progress. This particular matter of preliminary education the Council ought to settle, and at once. He denied the Council's right to take away any examining body's privileges and defended the action taken by the body he represented, whose examinations were not in any way lenient. Dr. Storrar's abuse of remanets was unfair. A young man who passes in a few subjects creditably ought not to be forced to undergo examination in them again. The system was introduced in the interests of students, and often capital papers were written at a second test. He had ascertained that many candidates who exhibited deficiencies in grammar and spelling held University certificates of preliminary education. The College of Surgeons of Edinburgh would resist any attempt of the Council to limit its privileges, and an appeal to the Privy Council should be forced. They should pause before raising the standard in any way to starve the supply of practitioners.

Mr. Teale moved, as an amendment to Dr. Storrar's motion, "That a committee be appointed to draw up a series of propositions to be submitted to the Council, which shall embody the various motions on the programme in reference to preliminary examinations, and such other questions on the same subject as it shall seem desirable to such committee to submit to the vote of the Council: this Report to be brought up at the opening of the meeting on Friday, in order that a distinct vote may be passed upon them during the present session; and that the committee consist of the following members:—Mr. Teale, Chairman; Dr. Humphry, Dr. Storrar, Dr. Andrew Wood, Mr. Turner, Dr. Leet, Rev. Dr. Haughton, Dr. Fergus.'

Dr. Wood seconded the amendment.

Dr. Haughton thought a committee could not deal efficiently with so big a question. He agreed that the preliminary examination was overloaded.

Dr. Rolleston advocated the appointment of a small committee to report next session.

Dr. Storrar defended the amendment.

Dr. Fergus said he had quoted the General Medical Council's figures before a Royal Commission to show the examinations were deficient. He thought it necessary to adopt a plan of filtering candidates, by which men unqualified to succeed in medical work should be rejected, and only those *mentally* fit be passed.

Dr. A. Smith would vote against the motion, and thought time would be lost by accepting the amendment.

Dr. Storrar explained that the report quoted by Dr. Banks in reference to Queen's University speaks of the first professional examination, and has nothing to say of the preliminary. Many difficulties he admitted beset secondary education in Ireland, but these were about to be removed. Dr. Pyle had misunderstood his remarks about Durham University. The creation of a special examination for medical students was censured by the Council's visitors. As to Edinburgh, he was surprised it was still content to accept any certificate approved by the Council in lieu of its own. He disagreed from Dr. Wood that agitation for reform obstructed improvements.

The amendment being put to the vote, was agreed to, and then carried as a substantive motion.

Alterations in the standing orders were then deferred for discussion, and applications for registration from Mr. John Dwyer and Dr. W. W. Ireland were sanctioned.

The case of G. F. Trotter, who was convicted of manslaughter, and sentenced to six months' imprisonment with hard labour, on January 29th last, was heard, and the evidence being read, strangers were requested to withdraw, while standing orders were, on the motion of Dr. Andrew Wood, suspended till the business before the Council should be completed.

Resolved:—"That the Council do not see fit to erase the name of George Frederick Trotter from the Medical Register."

The Council then adjourned.

Third Day.

The minutes of the preceding day having been read and confirmed,

Dr. Humphry moved the adoption of the Report of the Committee on Ophthalmology and Midwifery.

Rev. Dr. Haughton moved a resolution to the effect that the Council recommend a minimum knowledge of midwifery be exacted from candidates for any licence. He objected to the acceptance of the report, because he thought harm would arise from deferring definite action with regard to midwifery. The subject, he declared, was too important to be shelved, but he did not care how the subject of ophthalmology was treated. He would attach little importance to attendance on lectures, but attention to practical midwifery he would emphatically insist on. The subject had been impressed on him by reason of the inadequate qualification of ships' surgeons in this respect, and the frequency of cases in which midwifery experience is necessary to right treatment. He would fix the minimum of labours to be attended at thirty, and a six months' course of lectures. Dublin University had long adopted this rule, and it had worked well; a smaller number of cases would probably not afford sufficient experience. Ophthalmology he regarded as an accomplishment infinitely inferior to midwifery. Dublin instituted degrees in obstetric medicine eight or nine years ago, and pending legislation, Dr. Haughton demanded that the Council should act so as to place midwifery on its right footing.

Mr. Macnamara, seconding the motion, said the R.C.S.I. was as keenly alive as Dublin University to the importance of midwifery. No student was allowed to come up for a surgical qualification until he presented adequate proof of experience in midwifery. As President of the Irish Medical Association he ascertained that 95 per cent. of cases of charges of malpraxis were consequent on inexperience in midwifery. In the last year or so the College of Surgeons had increased the number of cases to be attended from six to thirty. He would suggest arrangements by which every student should see the full number of labours by more than one attending the cases. He did not want the Council to advise the *number* of lectures or cases to be attended, but simply to endorse the principle of the motion.

Dr. A. Wood thought there was a general agreement in the terms of the motion. The question is whether the Council is prepared to name the number of lectures and cases to be attended. This, he thought, was not its function. At most teaching centres courses of lectures are delivered, but it would be ridiculous to require—in Scotland, at any rate—thirty cases to be attended. He deprecated joint attendance at labour cases by young students, but acknowledged the importance of the matter fully.

Dr. A. Smith had always considered midwifery more essential to a young practitioner than any other specialty. The number of lectures was not important, but practical ex-

perience most highly so. The Council should do all it could to ensure adequate instruction in the subject. The Colleges of Surgeons and Physicians in Ireland, and of Surgeons in England are the only bodies which grant a special licence in midwifery after a special examination. The Local Government Board of Ireland demand a proof of special qualification in the subject from candidates for posts under it in the medical service of the country. At the maternity connected with Sir Patrick Dun's Hospital in Dublin students go to labour cases with experienced midwives, but never two students together.

Mr. QUAIN denied that the Council undervalued the subject of midwifery. In several places it distinctly urged the importance of the subject as part of medical education. He believed thirty or forty lectures enough to give the outlines of midwifery.

Mr. SIMON pointed out that the Report does not call on the Council to adopt hard and fast lines as to the amount of teaching to be given. The committee saw no reason for treating midwifery as an exceptional subject. Moreover, ophthalmology is not put on an equality with midwifery, although mentioned in the same report. They are treated in a different manner.

Dr. BANKS, though supporting Dr. Haughton's motion in principle, could not support his demand for thirty cases.

Dr. HAUGHTON would be content if the Council would accept the motion he introduced without specifying the number of lectures or of cases to be attended. He would insist only on a course of practical midwifery. His opinion on this point was endorsed by the College of Physicians of London, who desire to increase the practical instruction rather than the courses of lectures. The Apothecaries' Society of London, too, express disapproval of the meagre practical instruction in this subject. Dr. Haughton denied that he wanted the Council to pursue any exceptional course —it was the same as that followed for anatomy and surgery.

Prof. HUMPHRY endorsed Mr. Simon's remarks. The Committee made no reference to the relative value of midwifery and ophthalmology. The question before the Council was whether midwifery was to be put out of the level of other subjects. Dr. Haughton's desire is fulfilled by every examining body which requires instruction in practical midwifery. The Council makes no special rule as to the subjects of anatomy and surgery, and ought not to with regard to midwifery.

Dr. Haughton's amendment being put and lost, the original motion was carried.

PRELIMINARY EDUCATION.

The Committee appointed yesterday presented their Report, recommending the order in which the motions as to preliminary education should be discussed.

Dr. LEET introduced the first resolution :—"That on and after the first day of January next (1881) Greek be included among the compulsory subjects of the preliminary examination for medical students." The Court of the Apothecaries' Hall in Ireland are not, he said, prepared to lower the standard of their examination, as they must do if they submitted to assimilate these examinations to those of many other bodies. He quoted authorities in support of his view of the importance of the study of Greek as a subject of preliminary education. The Council, he said, had failed to redeem a promise contained in a resolution that Greek should be made a compulsory subject of examination in 1869. The Apothecaries' Society had no desire to continue their examinations, burdensome as they are, but there was nothing to replace them.

Mr. MACNAMARA seconded the motion.

Dr. AQUILLA SMITH pointed out that Greek is an optional subject, by the Council's standing order. He believed the test of a candidate's knowledge on this subject is very often a farce, and that little good accrues from insisting on it.

Dr. STORRAR said his chief reason for giving up the battle of Greek was a conclusion forced on him that the demand for modern education is so great that it is useless to insist on classical instruction. Such modern education includes Latin, English, mathematics, and physics. The demand for this kind of training is so great that the University of London substituted French or German as an alternative subject for Greek, and without undervaluing Greek as a mental training, German may be said to have an important bearing in the same direction. Seeing the limitation of the time of study, he would not like to see Greek made compulsory.

Mr. SIMON said no one could assert Greek was a necessity to a medical man. He would be the last to under-estimate its importance, but it would be eminently unfair to insist on it being made a compulsory subject. It was true a medical man ought to be a highly-cultured gentleman ; but pressing the doctrine too far would be to unduly reduce the supply of men to enter the medical profession. The minimum of preparation with which a man can learn medicine in four years is the standard to which the Council should address its attention.

Prof. ROLLESTON.—The question is measured by money ; the omission of Greek in schools arose through a feeling that it *paid* less well than the modern side with the view of equipping scholars for their life work. He strongly defended the study of Greek as tending to the higher culture of students, but he could see reasons against insisting on Greek as a compulsory subject. In Germany at the present time there is, he said, a reaction against the unlimited study of the language. He could not vote for the motion, to his regret.

Dr. FERGUS urged that many sciences bearing on medicine are as intellectual exercises as valuable as Greek, which subject he would have left optional.

Dr. HAUGHTON defended the study of Greek on the ground that its abolition, as a compulsory subject of study, would degrade medicine to a lower rank than that held by law and church. Though the amount of Greek necessary to pass most preliminary examinations, this might be altered if the Council sanctioned the subject. In a somewhat lengthy speech he defended the study of Greek, and concluded by saying he should vote for the motion.

Dr. BANKS supported the motion. The downward progress of the profession, he felt, would be hastened by omitting Greek from the curriculum. If the motion be not carried, he feared the profession would be lowered and degraded.

Dr. PETTIGREW said he considered other subjects, especially scientific ones, were capable of expanding the limits of the human mind as effectually as the study of Greek. He did not want to exclude Greek, but to keep it optional.

Prof. TURNER, while feeling the loss of Greek would be a severe blow to professional status, felt also that the signs of the times demanded acquiescence in the demand so general that Greek be not made a compulsory subject of any examination. The fact that classical studies had hitherto been almost solely rewarded by University and other prizes led to the better class of students at schools and colleges even yet preferring to follow out a classical rather than a modern course. Some time ago a special syndicate at Cambridge reported to the University that it would be well not to retain Greek as a compulsory subject for pass examination. Preliminary education must be carefully dealt with. By raising its standard unduly the number of entries into the profession will fall below a necessary number, as it once did following the Council's action. By extending the area of subjects to be taught the precision of knowledge will be reduced. Regretfully, therefore, he felt compelled to vote against the motion.

Dr. A. WOOD said he hrd been an examiner in Greek for some years, and his experience led him to the conclusion that but few men voluntarily take up the language. The knowledge of Greek roots given in schools generally is sufficient to give students an insight into technical terms.

Sir WM. GULL urged it would be dishonest to require a man who would enter on a country practice to be a Greek scholar. Unless taught well it is useless, and is a sham, and for it to be taught well is impossible to an ordinary medical man. The Council's duty is to make honest reputable practitioners, and this it will not do by demanding unusual accomplishments.

Sir JAMES PAGET thought it very unfair to assume a man cannot know medicine without a knowledge of Greek, especially since the knowledge he can get as a medical student must be meagre and fragmentary. If he could have a valuable and accurate knowledge it would be an inestimable boon, but a "smattering" utterly useless. The matter with science, mechanics, and chemistry, *e.g.*, is very different. The knowledge he has of these must *increase* as he progresses in life, but this is not the case with Greek, which must be constantly studied *alone* even to be kept up. He could not support the motion.

The PRESIDENT said the question at issue was highly important as involving the interests of the profession. He had consulted three eminent classical scholars, who unanimously agreed that teaching a smattering of Greek could not avail to improve the medical profession.

On a division the motion was lost.

Dr. HAUGHTON next introduced a motion to the following effect :—

"The General Medical Council being of opinion that the existing Preliminary Examination in Arts is unsatisfactory and insufficient, propose to replace it by the following examinations :—

(1) "An examination, previous to registration, in the following subjects only :—(*a*) English ; (*b*) Arithmetic ; (*c*) Latin ; (*d*) Elements of Geometry ; (*e*) Elements of Algebra.

(2) "An examination to be passed not later than at the end of the first year of professional study, in the following subjects :—(*a*) Greek ; (*b*) Elements of Mechanics.

(3) "An examination to be passed not later than at the end of the second year of professional study, in the following subjects :—(*a*) French or German ; (*b*) Elements of Hydrostatics and Optics."

He said he was led to take this course because of feeling that the preliminary examination is overloaded. He would diminish its extent in the hope of making students more accurately prepare for it. He feared his proposal to retain Latin would meet the fate accorded to Dr. Leet's motion in favour of Greek. His desire was to make the preliminary examination *thorough*, and he would be willing to omit Latin also, to increase the extent of the English and mathematical subjects. A sound and perfect knowledge of his own language, and of elementary mathematics, he thought enough to enable a young man to be a competent medical student.

Dr. LEET having seconded the motion,

Prof. ROLLESTON objected to the multiplicity of the examination proposed by Dr. Haughton. There was no excuse for keeping a student under the harrow so long. The subjects can all be included under the preliminary examination, and the encouragement the change would give to the "remanet" system indefensible. He concluded by moving an amendment to negative the motion.

Mr. TEALE and Dr. PETTIGREW having spoken,

Dr. Rolleston's amendment was carried.

Professor TURNER moved :—

"That the Preliminary Examination should be raised to the following minimum standard :—

(*a*) English to include Literature, History, Grammar, Composition.

(*b*) One ancient language, either Latin or Greek.

(*c*) One modern language, either French or German.

(*d*) Arithmetic, including Vulgar and Decimal Fractions.

(*e*) Elements of Mathematics, comprising Algebra, including Simple Equations, Geometry, first three books of Euclid or the subjects thereof.

(*f*) Elements of Mechanical Philosophy, comprising Statics, Dynamics, Hydrostatics, and Optics, it being understood that the examination in this branch

(*g*) May be passed either as Preliminary, or as part of the first Professional Examination."

Dr TURNER explained that he was asking the Council to take up a new position in seeking its sanction to make French or German a compulsory subject. He thought the course a necessary one, as also the addition of one book of Euclid. The Elements of Mechanical Philosophy he felt to be an actual necessity to the student of physiology, and he urged the acceptance of his motion in this respect. But since all schools do not teach this subject, to enable it to be included fairly in a preliminary examination, it would be advisable to grant leave to the student to pass in natural philosophy subsequent to registration as a medical student. Dr. Turner moved the adjournment of the debate.

FOURTH DAY.

The minutes of the preceding day's business were passed.

PRELIMINARY EDUCATION.

Prof. TURNER said that since yesterday he had considered the Council had better consider his motion in committee.

Mr. SIMON seconded the proposal.

Dr. A. WOOD requested that Prof. Humphry afford an explanation concerning the Report of the Committee on Mechanical Philosophy.

Prof. HUMPHRY said that the subjects could not be included in the first professional examination, which is already provided for. The subjects therefore, can only be passed at the preliminary examination. Moreover, they are not included as subjects by many of the chief examining bodies. Hydraulics is not accepted by any of the boards, and hence, to enforce the regulation would be to throw the whole educational system in confusion. The Executive Committee accordingly referred the matter for the further consideration of the Council. It could not be expected that examining bodies would alter the whole scheme of their tests at the request of the Council, and the latter should pause ere it farther strained their compliance.

Mr. SIMON was of opinion that the course of the Executive Committee was improper.

The PRESIDENT reminded Mr. Simon the Council was in committee, and comment on the action of the Executive Committee was out of place.

Mr. SIMON continued his remarks, to the effect that the speech of Prof. Humphry would have been appropriate last year on first discussion of the subject ; he was happy that the debate on Mr. Turner's motion would settle the question. He thought the Executive Committee should be censured.

Prof. TURNER proposed to take the items of his motion in their order. The recommendation admitting the sufficiency of an Arts degree in lieu of a preliminary examination would obviate the difficulty of requiring a modern language as a subject to be passed. He proposed to introduce two new compulsory subjects, viz., a modern language and mechanics. He would extend the time at which the rule came into force beyond Jan 1, 1881. He moved the first item.

Dr. ROLLESTON repeated that the subject ought to be referred to a special committee to consider all the points carefully between that and next session. He had been informed that only three medical schools in London possessed courses in natural philosophy, and for them to pass Dr. Turner's motion would be to affect nearly all the schools in the country.

Dr. TURNER objected that the course pursued by Dr. Rolleston was out of order. A desultory discussion on the wording of Dr. Turner's motion was followed by an amendment from Dr. Wood, seconded by Dr. Haughton, "That the existing regulations remain in force," regarding, that is, the English subjects of preliminary examination.

Dr. ROLLESTON defended the introduction of literature on the ground of culture, and as being calculated to elevate the status of the profession.

Sir WM. GULL thought to insist on such a subject unwise. The Council did not desire to limit any man's attainments, but they had to fix a *minimum*, and this must not be too high.

Mr. TEALE defended the amendment.

Dr. HALDANE thought an elementary knowledge of literature, history, and geography should be compulsory on every candidate for the medical profession. Only by insisting on such knowledge would the professional status be maintained.

Sir JAS. PAGET considered the Council might reasonably demand more now than formerly at a preliminary examination. As schools improved the preparation of candidates progressed *pari passu*, and the Council should make first and earnest use of educational improvement. Students will not read what is not required.

Mr. SIMON agreed with Sir Jas. Paget. He thought the existing examinations should be made stricter as far as they go. The Council could not insist on a knowledge of subjects not essential to the study of medicine. The English language is so, but literature is not.

Mr. TURNER was much disappointed that an amendment should have been moved to leave things as they were. Since, six years ago, the resolution came into force, great changes had occurred in education in the three countries. He could not conceive a good school where English history is not studied. The amendment implied a wish to lag behind the times. He felt the credit of the Council was at stake.

Sir WM. GULL thought a strict adherence to the Council's requirement's would effectually settle the question—make the present examination *thorough*.

Dr. ANDREW WOOD concurred in Sir Wm. Gull's opinion.

Prof. ROLLESTON quoted from the *Cambridge University Reporter* to the effect that the German Association of Doctors pronounced against permitting men to enter the medical profession with the little preliminary training they usually possess.

He quoted also Dubois Reymond and other authorities to the same effect. He hoped the Council would not sink the English profession to a position of inferiority.

Sir JAMES PAGET said the Royal College of Surgeons now examined in English grammar, composition, geography, and history. The Council can help the schools by passing recommendations, and the schools would help it.

Dr. PITMAN hoped the present regulations would be amended. How, he asked, could the Council be assured of a higher standard of present tests being attained. This would only follow the addition of new subjects. Dr. Pitman showed, by quoting from the minutes, that a feeling had often arisen in the Council in favour of improving the preliminary examinations. He should vote for the motion and against the amendment.

Dr. AQUILLA SMITH was followed by Mr. MACNAMARA, who cautioned Mr. Turner against the difficulties which would arise with the subject of history if it were included in his scheme.

Dr. BANKS having spoken, Prof. Turner's motion was read, modified to include literature, geography, and history, but Dr. Wood objected to the alteration.

Dr. ANDREW WOOD'S amendment was then put to the vote, and was carried, the numbers being—for, twelve; against, eight; neutral, four.

Dr. HAUGHTON moved an amendment to add to the second recommendation—candidates shall be required to pass in modern geography or English history.

Dr. ROLLESTON considered the same objections applied to the subject named by Dr. Haughton as to literature, and he would move, as an amendment, that an option be allowed between geography, history, and literature.

The PRESIDENT pointed out that the vote of the Council in committee had already limited the question of the English preliminary examination.

Dr. STORRAR urged that Dr. Andrew Wood's amendment was not yet passed as a resolution, and any amendment on it was in order.

The amendment of Dr. Wood being put as an original motion, was carried.

Dr. HAUGHTON'S amendment then became a substantive resolution, and Dr. Rolleston moved his amendment to add literature to geography and history.

Mr. SIMON dissented from the proposal. He desired to see the preliminary examination based on an appreciation of the importance of natural science to a medical student, and he felt it wrong to compel literature, geography, and history, valuable as they are, as essential subjects.

Prof. TURNER said he occupied an entirely different position from Mr. Simon. As the time of the student is occupied with scientific studies, he is prevented from literary studies, which, if not pursued early, are never pursued at all. Some literary culture they should have, and he would second Dr. Rolleston's amendment.

Dr. A WOOD would assure the Council only a certain limited amount of knowledge could be extracted from a student, and that they were proceeding to insist on too much and too many subjects. The attention of a medical student should be confined to the subjects which will aid his medical career, and the burdens laid on them should be thoroughly borne. The examinations ought to be efficient and strict. He would vote against the motion.

Prof. HUMPHRY complained that too many subjects are taught and insisted on already. The best education is that which instructs in a few subjects well. He would even revert to old systems, feeling that it is far better to restrict examinations and so improve education and knowledge. The optional system he did not think worked well.

Mr. MACNAMARA entreated Dr. Rolleston to withdraw his amendment. By so doing so he might ensure the passing of Dr. Haughton's motion.

Dr. ROLLESTON insisted that literature would materially assist to make a medical student a good practitioner by giving him social advantages and ability to maintain his own in cultivated circles.

Sir WM. GULL could not see that geography was any intellectual test of a man's fitness to be a doctor. He wanted only such subjects included in a preliminary examination as would serve to test his intellectual quality.

Sir JAS. PAGET thought the *best* test of intellectual capacity is by determining how a boy had learnt any subject at all.

Dr. QUAIN spoke in favour of the motion.

Dr. Rolleston's amendment being put to the vote was lost, and Dr. Haughton's motion was then carried.

Dr. TURNER moved his second point, that an examination in one ancient language form part of the scheme.

Sir JAS. PAGET seconded the motion.

Rev. Dr. HAUGHTON said he should move an amendment that, "In the opinion of this Council the English language is the only language which ought to be included in an English preliminary examination."

The committee of Council then resolved, and the report of the finance committee was proceeded with.

WEDNESDAY, JULY 14, 1880.

THE GENERAL MEDICAL COUNCIL AND PRELIMINARY EDUCATION.

THE greater part of the thirtieth session of the General Medical Council will have been occupied with discussions on a subject over which it can expect to exert only a minimum influence, while there are pressing for notice and decision questions of inconceivable importance. The preliminary education of the medical student is undeniably a serious matter in connection with the decision of a fitness for the practice of medicine; but the utterly false notion which influences the vote of the Council is, that the position of the medical profession is to be immediately improved by insisting on a higher standard of general education. It is true that the average intelligence of the practitioner must be largely dependent on his early

training and the capacity to derive advantage from it; and equally true that the best men to entrust with the cure of disease are those best qualified to shine in any intellectual sphere; but it is strangely fallacious to hope or to expect that the better class of students, round whom the General Medical Council yearns to clasp its encircling arms, is to be drawn within the magic circle of its own creating, by the aid of abortive efforts to build higher and higher the gateway which guards the entrance to a medical curriculum. The better class of students, fortunately for themselves, are such as Sir William Gull's "intellectual test" would readily discriminate; and they are as little likely as Sir William Gull himself to be deluded by the semblance of a reality which the Council seems bent on spending its existence over creating. Howsoever high the standard of preliminary examination may be raised, the status of the medical profession will remain what it is, unless concurrently some means be devised to ennoble the practice of medicine itself. Reforms are urgently demanded *in* the profession, and not around it; when these have been effected, and a medical man can enter on the duties of his position with the feeling that he is a recognised unit of an honourable aggregate, and that he is at least as respectable as his neighbour, who is a parson or a barrister, then—and not till then—will the title of Doctor be something more than a qualification to prescribe physic. This improvement in the public estimation of physicians and surgeons, however, is not to be obtained by dictating to schoolboys how much they must comprehend of the fine distinctions which separate classical English from Cockney prose; or by defining the maximum amount of ignorance to be tolerated in a candidate for medical distinctions. All these might well be left to settle themselves, as they naturally would if they were not thus constantly coddled and nursed by the twenty-four gentlemen who meet at a cost of some two hundred pounds per day to regulate the affairs of the medical profession.

There are crying evils without end to be redressed *in* the profession—evils which each day are plunging their ill-fated victims deeper and deeper in the waters of public contempt. Let the General Medical Council waken from the doze of contentment it has for twenty years complacently indulged; let it consent to be alive, if only for one startling session, and open its eyes to the enormities that continue beneath the protecting ægis of its passive approbation. There is no difficulty in recounting the worst of these—*e.g.*, special hospitals and the abuses they foster and conceal. A Council on Medical Education even can bring consideration of such hotbeds of malpractice as many of the institutions termed special hospitals are within the scope of its powers, for are they not frequently enough plausibly put forward as centres of instruction?—and where, more than at many of them, does a student learn more surely or more swiftly to be guilty of the meanness, the disgraceful baseness, that have been again and again demonstrated in connection with them? When the outside public can learn to place implicit confidence in a medical man *because* he is a medical man, and when the term becomes a synonym for gentleman and man of integrity, then—and not till then—will the medical profession rank on a par with its sisters. And it is idle nonsense to talk of elevating it to this proud position by raising the standard of this or that *examination*. The sons of gentlemen will never in any numbers elect to practise medicine until they can feel a certainty that they will not thereby be degraded. In some few instances the love of science is too strong to permit even this feeling to withhold the seeker after truth from pursuing a path congenial to his nature. To this do we owe it that there are great men and good men who are doctors; while their numbers are strengthened by the addition of others who become ennobled by the calling they have adopted — whose souls have responded to the greatness of the things with which they have been called to deal. The two classes form the *élite* of the medical profession; the aim of the reformer is ostensibly to swell the numbers included within them, but the method hitherto pursued for its attainment has lacked the essential *element* of success—viz., a right direction.

Prof. Haughton and Dr. Leet should feel no discouragement at the refusal of the Council to adopt their demand that every medical man shall learn the elements of Greek; nor need Professor Turner feel chagrined that his proposal to insist on literary culture as a *sine quâ non* for a student of medicine has failed. Great minds crave to make the whole world great, and the mind of the General Council is true to its aspirations in the line it is following. The misfortune is that the line is a wrong one, and can never lead to practical good. It endeavours to reform where reformation can effect no beneficial result—it confines itself to the outer limits while within the barrier it is continuously repairing, corruption is progressing with fatal, because unchecked, speed. The Council may say it has no jurisdiction beyond the mere examination question, but this is disproved by its undisputed sway over all pertaining to the ethical proceedings of those included in its Register. By means of examinations it can influence only those who *are to be* medical men; by its judicial control over the Register it can purge the profession *in esse*. Mr. Simon, however, and the late Sir Dominic Corrigan, rightly appreciated the position of the Council; they saw clearly the weakness of its constitution, and they urged correctly the wisdom of its becoming either an absolute power or a disbanded corps. That it is impotent in itself, and has secured none of the authoritative power it must possess ere it can achieve great measures of reform, is continually being made clear. Dr. Andrew Wood can with impunity openly defy it to insist on anything; and unhesitatingly expresses the determination of at least one great corporation to submit to nothing more of its dictation than may be acceptable to that corporation's inclinations. A body with scarcely the shadow of authority can hope to work to small purpose indeed; its *prestige*, at no time great, will be nohow augmented by the latest exhibition of its weakness. The miserable pretence of improving the profession of medicine by raising the standard of preliminary education is a lamentable evidence of the short-sightedness which has distinguished its whole career.

THE DUBLIN DEATH-RATE.

The Report of the Royal Sanitary Commission, to

which we referred last week, has not yet been issued to the general public, although a few copies have been circulated, and its contents are known. Meanwhile its appearance in abstract in our columns and elsewhere has given a stimulus to the sanitarians of Dublin, and there seems to be some hope that the citizens will now bestir themselves to seek for a practicable remedy to the existing disgraceful condition of affairs. We learn that the Council of the Royal College of Surgeons in Ireland has, on the motion of Dr. J. K. Barton, resolved, "That it is desirable that an expression of opinion should emanate from this Council regarding the causes which have produced, and are still producing, the unhealthy state of the city, and the abnormally high death-rate in Dublin. For this purpose, that a committee be named to confer with the College of Physicians, and to make a report to this Council, as soon as possible, with a view to further action in this matter."

We earnestly trust that the co-operation of the Colleges with the Dublin Sanitary Association may have the effect of, at length, providing a practicable remedy for the appalling insalubrity of Dublin. During the past week the death-rate of the city and suburbs, taken together, was 33·5 per 1,000—nearly double that of London (18·0), or Glasgow (19·8), and one-third more than that of Edinburgh (22·4). The ratio of mortality was only exceeded by two continental and foreign cities out of twenty-six whose death-rates are recorded. The mortality in Dublin was proportionately much greater than that of such unhealthy cities as Calcutta, Madras, Copenhagen, Naples, and New York.

There were 63 deaths from zymotic diseases registered, being 8 more than in the preceding week, and 27 over the average for the same week *of the last ten years:* they comprise 14 from small-pox, 8 from measles, 19 from scarlatina, 1 from quinsy, 5 from whooping-cough, 5 from fever (2 typhus and 3 typhoid fever), 2 from diarrhœa, &c. The registered deaths (14) from small-pox are 5 less than in the preceding week, but are equal to the number in the week ending the 19th ult.

In discussing this painful subject, we call attention to the following recommendation of the Royal Sanitary Commission, published by us last week :—

"That, considering the extensive sanitary improvements necessary in Dublin, we are of opinion that the superintending medical officer of health of the city should devote his whole time to the duties of his office."

It will be recollected that when the job of pensioning a superintendent medical officer of health who never did any duty, and appointing in his stead a superintendent medical officer who was too busy on other affairs to discharge his functions with any efficiency, we offered just the same suggestion as the Commissioners have now made; and we warned the citizens that the pensioning and the appointment were both rank jobs, and that the practical effect of those jobs was to leave the city of Dublin without a superintending health officer.

It would seem that our prediction has been fully realised, for we observe that Mr. James Boyle has assumed the functions of the superintendent medical officer, and has, in that capacity, issued a report on the small-pox epidemic, and has given the world the benefit of his valuable advice thereon. The only passage worthy of notice in this report is the following:—

"I cannot avoid observing that all accepted theories as to climatic influences, &c., have been confuted by existing facts. It may be that the vaccine matter has lost its efficacy, or that the operation of vaccination may be less perfectly executed than heretofore."

We should feel greatly interested to learn the authority upon which Mr. James Boyle undertakes to inform the world that "vaccine matter has lost its efficacy, or that the operation for vaccination may be less perfectly executed than heretofore;" and we would add that that gentleman would give additional weight to this remarkable dogma if he would explain to us the special qualification—medical or scientific—which he possesses to enable him to express an opinion on any such subject. No doubt his observation that "climatic influences" are to blame for the mortality is perfectly true, but we altogether differ from him in his assumption that "&c." is not responsible for the spread of disease within the city. This comprehensive abbreviation "&c." we interpret to mean the filthy and neglected state of the tenement houses and the streets which is tolerated by the Corporation, and which, no doubt, bashfulness prevents Mr. Boyle from more exactly particularising, and we, therefore, beg to refer that gentleman to the conditions included within the expansive scope of "&c." for a full and complete elucidation of the causes of disease within the city. Finally, we have formed the determination to endeavour, before our next issue, to ascertain whether there exist any superintendent or consulting medical officers of health for the city of Dublin, and whether the gentleman who has undertaken the small-pox reporting for the Corporation has really absorbed these two offices.

We observe from the local papers that the Corporation has adopted recently a new code of sanitary bye-laws, which, so far as the newspaper reports inform us, appear to be altogether inadequate for their purpose. In the debate upon the proposition to adopt this code, the Lord Mayor said that he had been through some of the tenement houses of Dublin within the last few days, and he confessed he had been appalled at their condition. The scenes of filth he witnessed had been beyond description, and had made him determined, as far as he could, to do something by way of remedy. He did not believe that any bye-laws or prosecutions could be of much effect until the houses were destroyed altogether; but it really made one wonder how human beings existed at all in such hideous filth.

We should hardly suspect his Lordship of joking upon such a subject, but really there is a grim funniness about the Lord Major's horror over his newest discovery which suggests that he must have been speaking ironically. Be it known that the Lord Major is, and has been for many years, the Chairman of the Public Health Committee; that the Dublin sanitarians have, during his whole tenure of office, never ceased from (metaphorically speaking) thrusting the filth of the Dublin tenement houses down the throats of his Lordship and of the Public Health Committee; that the Lord Major was the man who endeavoured to prevent the Royal Sanitary Commission from

inquiring into the state of these tenement houses, and that his Lordship, his Committee, and his officers have been for years, one and all, fixed in their determination not to see the state of affairs which now exercises his indignation and horror.

We congratulate his Lordship on his first inspection of the less fragrant parts of the city under his rule, and we congratulate the citizens upon the extraordinary conversion which his olfactory investigations therein have effected.

Notes on Current Topics.

The Rations of our Soldiers.

We are glad to hear that the Right Honourable the Secretary of State for War has sanctioned an additional allowance of four ounces to the three-quarters of a pound of flesh *with bone* that for a long time past has constituted the daily meat ration of the British lion, as represented by the infantry of the line, and we congratulate Private Thomas Atkins accordingly. Perhaps some few of our readers are not aware that it was only in 1793 that our soldiers were allowed more than one meal per day, or that men sick in hospital were granted anything more suited to their individual cases than the salt pork and the rum upon which they, like their comrades in barracks, were forced to subsist. Army doctors had indeed protested against this state of things for many years, but without result; but at last their voice was listened to, and a second meal per day granted to the soldier, namely, breakfast, of oatmeal gruel. So things went on till 1809. In that year, on the recommendation of "the doctors," tea and coffee as substitutes for oatmeal gruel were, "on sanitary grounds," to use the phraseology of the present day, issued to troops in Walcheren; but that expedition over and collapsed, the luxury of tea or coffee was soon withdrawn, nor was it till 1817 that both took their places as part of the rations for soldiers and for sailors. Many more years had again to elapse before any further improvement was made in the manner of rationing soldiers. In 1845, the "evening meal" of tea and bread was sanctioned for troops in the United Kingdom, in this respect adopting for home service the custom that had for "any length of time" been followed in India under the *régime* of the dear departed John Companee Bahadur Jee! Now, in 1880, another leaf is being taken out of the book of Indian experience; the fact has thus been acknowledged that if men are to fight well, and bear up against fatigues, they must be fed well. Nor is this the only point regarding the hygiene of troops, as in other abstruse matters, that light comes to us from the East.

The London Ophthalmological Society.

With reference to our complaint that this Society has appropriated the prestige to which it would be entitled if it were a Society of the United Kingdom, a correspondent writes to one of our contemporaries as follows:—"I was glad to see Mr. Solomon's letter on the Ophthalmological Society in your columns last week. I have reason to believe that it is bearing fruit. It ought to be added, however that his motion was lost by *one* vote, his opponents being chiefly young men. Ten voted for the resolution, and eleven against. I believe only four country members were present at the meeting."

It would seem from this statement that the restriction of this "United Kingdom" Society to the London postal district was the deliberate act of a clique, and we take leave to inform these gentlemen that, in assuming to speak for the ophthalmology of Great Britain and Ireland, they are taking upon themselves pretensions to which they have no right whatever.

Action against a Coroner.

At Tullamore, last week, an important libel action, which was listed for hearing in Dublin, was settled. One of the relieving officers of the Tullamore Union sued the senior coroner of the King's County for £1,000 for libel. The circumstances were of rather an extraordinary nature. An inquest was held on a resident in plaintiff's district who was in receipt of out-door relief, and the defendant was alleged, when forwarding the depositions to the Chief Secretary, to have falsely and maliciously inserted a statement to the effect that the parish priest had said of a portion of the plaintiff's evidence, "This is nothing short of perjury." It was denied these words were ever used. Defendant pleaded privilege, but on a demurrer this plea was overruled. Amongst the witnesses summoned were Mr. James Lowther, the President of the Local Government Board, and other officials. The settlement arrived at is the payment by the coroner of £65, to include plaintiff's costs.

A Menstruum for Salicylic Acid.

In the *Louisville Medical News*, May 1, Dr. Springer states that salicylic acid is readily soluble in effervescing Vichy or Seltzer water, the former, from containing an excess of alkaline carbonates, being preferable. The acid is put into a tumbler first and mixed thoroughly with a small quantity of water to prevent its floating, and the glass then filled with the effervescing water and the liquid drunk off. When perfectly dissolved it is said to have a very pleasant, exhilarating, pungent, and sweetish taste.

Apparent Death as a Result of Asphyxia.

Medical journals occasionally inform us of wonderful resuscitations brought about by the persistent use of artificial respiration; but two, lately reported to the Academy of Sciences, Paris, by Dr. Fort, Professor of Anatomy in the Ecole Pratique, are especially noteworthy, and teach us to persevere in any efforts we may make to bring back signs of life. In the case of a child three years old, who had already been placed in his shroud, Dr. Fort commenced the use of artificial respiration three and a half hours after apparent death. After four and a half hours of steady work the child was brought back to life. The other case was that of a drowned man, who had been under water for twelve minutes before the body was recovered. Artificial respiration was commenced an hour afterwards, and after being kept up for hours the man was restored to life. The report of the meeting of the Academy does not give the details of the child's case before the ap-

pearance of the apparent death, nor what prompted the doctor to commence the artificial respiration.

Milk and Consumption.

A VERY terrible danger has been exposed by Dr. Heath, President of the American Farmers' Club, who asserts that tuberculosis is a prevalent disease among animals slaughtered for food, and that cow's milk may be a ready vehicle for the communication of the disease. Fifty per cent. of the cows kept in large towns are declared to be thus affected, and that the little notice taken of the fact is consequent on the animals being slaughtered at a stage of disease in which it is not excessively developed. The truth of these statements will, of course, need confirmation, but in a considerable measure this has been already adduced by experiments in which small animals fed on milk have exhibited undoubted evidence of tubercle. These observations open up grave questions of impending dangers, since it would seem conclusively proved that young children may acquire constitutional taint from the food which is regarded as their staple diet. There seems but one certain preventive at present, and that is to thoroughly boil all milk used for feeding purposes, and this precaution, at the present time of year especially, ought always to be observed.

The General Council and its "Recommendations."

AN amusing incident took place on Friday during the sitting of the General Medical Council. Dr. Leet, in advocating the adoption of his proposal to make Greek a compulsory subject of preliminary education, reminded the Council of its previous action in regard to this question, and among other things drew its attention to a "recommendation" by which it was decided in 1867, that after the year 1869, Greek *should* be made a compulsory subject. It then became apparent that, according to the existing requirements of the Council there was a rule which provided for that which Dr. Leet sought to have introduced, but no member of the Council seemed either to be aware of this fact, or of the yet more significant one, that for a period of ten years this important recommendation had been a dead letter. In the multiplicity of its decisions, all bearing more or less on points of minor detail, it is perhaps not surprising that the oversight occurred. an omission more or less of the suggestion being a matter of inconsiderable moment.

Poisoning at Welbeck.

ON the occasion of a public sale at Welbeck, a number of people purchased meat from a refreshment stall arranged for the convenience of those visiting the place from a distance. Of these people a large number became subsequently sick, and four have actually died. The symptoms complained of were vomiting, colic, and diarrhœa. The first conclusion arrived at was that the ham sold at the refreshment stall had been diseased, it having been found that the majority of persons attacked had purchased food at it. The medical evidence, however, at the coroner's inquiry on the fatal cases, challenged this opinion, one witness giving it as his conviction that the attack was one of English cholera, this being supported by the discovery that some of the sufferers had not partaken of the supposed diseased meat. All those persons, however, who had eaten of it were subsequently ill. The circumstance yet wears the air of mystery, but a searching investigation is about to be made by Dr. Ballard, who has received directions to proceed to the place and report upon the occurrence. The verdict of the jury was to the effect that death ensued from choleraic diarrhœa, caused in their opinion by partaking of impure or bad food.

The Representative of Queen's University.

THE representative of Queen's University, Ireland, on the General Medical Council, in succession to the late Sir Dominic Corrigan, took his seat in the general assembly on Wednesday last for the first time. Dr. John Thomas Banks, the new councillor, is an M.D. of Dublin, Fellow and ex-President of the King and Queen's College of Physicians in Ireland, and a Member of the Senate of Queen's University. He was formerly King's Professor of the Practice of Medicine, and Clinical Professor of Sir Patrick Dun's Hospital. The Rev. Dr. Haughton introduced the new member, who subsequently joined in the debate on preliminary education.

Government and the Medical Council.

MR. JOHN SIMON, C.B., has given notice of a motion to call the urgent attention of the present Government to the unsatisfactory state in which the Medical Acts Amendment Bill was left by the late Parliament. Mr. Simon was certainly not encouraged when he attempted to direct the Council on Friday into the path it ought to tread just now. His proposal that it should wait for a settlement of its position ere it proceeded to frame new regulations for the licensing bodies to sneer at, was scouted as an unpatriotic suggestion to the Council to abdicate its functions. The punctilious manner in which these same functions are cherished by the gentlemen in Council is something amusing in connection with the heedlessness with which their attempts to legislate are received. Mr. Simon's plan has, at any rate, the merit of dignity and consistency.

The Study of Ophthalmology.

OUR readers will recollect that an influentially-signed memorial of ophthalmic surgeons was presented some months since to the General Medical Council, praying that ophthalmology might be added to the curriculum, and specially accentuated in the examinations necessary for a qualification. The memorial, which we printed at the time, dwelt upon the importance of the speciality and its semi-neglect in the educational system, and the Medical Council decided to send it to all the licensing bodies for their verdict upon it. The replies of these bodies are now published in the minutes of the Council, and we regret to observe that they are uniformly hostile to the proposal —not, indeed, upon the ground that ophthalmology does not deserve attention, but because they do not wish to increase the curriculum, or to intensify the examination. We cannot but sympathise with this view, though we

regret its application to the present case, and we look forward to a proper recognition of ophthalmology when the conjoint schemes have been made law, and are in course of construction. Meanwhile a little *emeute* has taken place in Dublin amongst hospital teachers in consequence of the anxiety of Trinity College to give importance to the speciality. The University of Dublin requires a special course of lectures on the subject from its candidates, and it has recently ordered that "certificates in ophthalmic surgery will not be accepted from any hospital that does not maintain permanently fourteen beds for ophthalmic cases only."

Now there are two facts in the light of which this resolution must be read:—1. That there is, we believe, but one hospital in Dublin which contains fourteen permanently-occupied beds for ophthalmic cases. 2. That the ex-Registrar of the Medical School of the University, who is a Fellow, and the adviser of the Board in all such matters, is a governor of that particular hospital, and its most active administrator. In view of these two facts the hospital surgeons of Dublin have been called to conference and, no doubt, to protest against the "fourteen bed" requirement.

Vaccination in Danger.

We are gratified to observe that the note of alarm which we sounded this day week in reference to Mr. Dodson's Bill for facilitating the dissemination of small-pox has been echoed in most influential quarters, and that there seems every prospect of an uprising in the profession which will defeat the foolish efforts of the President of the English Local Government Board to conciliate the little knot of vaccino-maniac M.P.'s who have seats at his side of the House. The Parliamentary Bills Committee of the British Medical Association has issued a petition against the Bill for universal signature. The English Poor-Law Medical Officers' Association, at the annual meeting, resolved, "That this Association feels that the success of such Bill would lead to the most disastrous results to the community at large, who, under the present system, where the operation is properly carried out, are fully protected from the ravages of small-pox." The London College of Physicians has resolved, "That the College, having considered the Vaccination Acts Amendment Bill now before Parliament, are of opinion that such a measure would, if it became law, be certain to encourage the spread of small-pox, to the great detriment of the community; and the College respectfully suggests to the Government the necessity of reconsideration on that important matter." Lastly, the Council of the Irish College of Surgeons has adopted the following petition on the subject, which will be presented immediately:—

"That your petitioners have learned with apprehension and regret that a Bill has been introduced into your honourable House which provides that the legal custodian of a child shall be exempt from all penalties attaching to a breach of the law which requires him to have such child vaccinated if he shall have been once prosecuted for such breach, and fined 20s., or twice prosecuted and fined in any sum.

"That your petitioners are convinced that if such Bill should become law it will afford great encouragement and facility for violation of the law of Compulsory Vaccination, not only by those who deny the efficacy of vaccination, but by the much more numerous and more important section of the people who are disposed to omit to have their children vaccinated simply from forgetfulness or carelessness; and your petitioners therefore believe that, as regards such persons, the passing of the Bill would be equivalent to the repeal of the law of Compulsory Vaccination.

"Your petitioners feel that, having regard to the prevalence of small-pox, not only in Great Britain and Ireland, but elsewhere, and to the fact that, for the second time within a recent period, a very serious epidemic of that disease now exists in the City of Dublin and in other places throughout, increased vigilance and stringency in the enforcement of compulsory vaccination and re-vaccination are very desirable, rather than increased inducements to violate that law, and they regard it as their duty to submit to your honourable House their well considered belief that the passing of the said Bill would prove greatly detrimental to the public health, and a formidable hindrance to the much-desired extension of vaccination in Ireland.

"Your petitioners furthermore humbly submit that the lives and health of the vast majority of her Majesty's subjects who entertain a full belief in the protective influence of vaccition, ought not to be subjected to the dangers of small-pox in deference to the erroneous opinions of the small minority who do not hold such belief, which result your petitioners fully believe would accrue from the passing of the said Bill.

"Your petitioners therefore humbly pray that your honourable House will not pass said Bill."

Registration of Disease.

At a recent meeting of the King and Queen's College of Physicians in Ireland, it was resolved, "That the College approve the principle of compulsory notification of infectious diseases, provided the duty of notifying is imposed only on the head of the family or owner of the house in which the disease occurs; and also the principle of registration of infectious diseases; and that the College will be glad to assist and co-operate in obtaining the necessary Parliamentary powers for securing the advantages which would, in their opinion, result from the attainment of an efficient system of notification and registration based on the lines indicated."

We understand that the subject is also under consideration by the Irish Medical Association.

The University of Dublin.

The following order has been made:—"That the professors of the School of Physics shall furnish to the provost and senior fellows, before December 10 in each year, a list of twelve names of persons considered by them qualified to act as extern examiners in the following subjects:—(*a*) Medical Pathology, three names; (*b*) Therapeutics, three names; (*c*) Ophthalmic Surgery, three names; (*d*) Midwifery, three names." The above resolutions have received the assent of the Board of Trinity College.

Dr. Mapother, late President of the Royal College of Surgeons in Ireland has been elected President of the Statistical Society of Ireland.

The statement that a severe epidemic of small-pox has broken out in Christiania, the capital city of Norway, is contradicted. The only patients affected were some unvaccinated children.

On Thursday last the Lord Mayor of London and the Sheriffs laid the foundation-stone at Margate of additional buildings for a branch establishment of the Deaf and Dumb Asylum, Old Kent Road.

THE *United Service Gazette* has reason to believe that the vacancy on the active list of Deputy Inspectors-General of Hospitals and Fleets, caused by the death of D. I. G. John Elliott, will be bestowed upon Fleet-Surgeon W. L. Gordon, M.D., now in charge of Haulbowline Hospital.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Portsmouth 12, Bradford 14, Wolverhampton 14, Nottingham 15, Plymouth 15, Leeds 16, Sheffield 17, Bristol 17, Newcastle-upon-Tyne 18, Brighton 18, Birmingham 18, London 19, Manchester 19, Hull 20, Salford 21, Leicester 23, Sunderland 24, Norwich 25, Liverpool 26, Oldham 30, Dublin 34.

THE annual meeting of the Sanitary Institute of Great Britain was held on Thursday last, at the Royal Institution, when Captain Galton, R.E., C.B., delivered an address on "Some Preventible Causes of Impurity in London Air." The Earl of Shaftesbury presided. In the evening the members of the institute dined together at St. James's Hall Restaurant, under the Presidency of Dr. B. W. Richardson, F.R.S.

A MEMORIAL has been signed by upwards of 800 persons, including Sir Henry Thompson, Dr. Risdon Bennett (President of the Royal College of Physicians), Mr. Darwin, Professor Huxley, Dr. W. B. Carpenter, and leading nonconformists, and presented to Mr. Gladstone, asking for the support of the Government to the motion of Mr. Roundell in favour of the complete abolition of the clerical Headships and Fellowships at Oxford and Cambridge.

THE annual death-rate last week in the large towns from the seven principal zymotic diseases ranged from 0·7 and 1·2 in Wolverhampton and Portsmouth, to 7·3 in Salford, 8·8 in Dublin, and 9·7 in Norwich. Scarlet fever showed the largest proportional fatality in Dublin, Salford, Norwich, Sheffield, and Bristol; measles in Sunderland, Leicester, and Salford; and whooping-cough in Liverpool. Small-pox caused 14 more deaths in London, 14 in Dublin, but not one in any of the other large towns.

A MEMORIAL brass, supported on a slab of black marble, has just been erected in the chapel of the Royal Victoria Hospital at Netley, to the memory of the late Surgeon-Major Shepperd, of the Army Medical Department:—"In memory of Peter Shepperd, M.B. Aberd., Surgeon-Major Her Majesty's Army, born at Leochel Cushnie, Aberdeenshire, 25th August, 1841, who sacrificed his own life at the battle of Isandhlwane, Zululand, 22nd January, 1879, in the endeavour to save the life of a wounded comrade. Erected by his brother officers and friends."

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 18, Bombay 31, Madras 31; Paris 26; Geneva 21; Brussels 24; Amsterdam 20, Rotterdam 24, The Hague 15; Copenhagen 25; Stockholm 24; Christiania 19; St. Petersburgh 48; Berlin 38, Hamburg 23, Dresden 18, Breslau 31, Munich 33; Vienna 27, Buda-Pesth 41; Venice 24; Alexandria 40; New York 24, and Baltimore 28 per 1,000 of the populations. Small-pox caused 48, measles 39, and typhoid fever 26 deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

REGISTRAR-GENERAL'S REPORT.—According to the weekly return of births, deaths, and marriages in the eight principal towns of Scotland, the death-rate for the week ending with Saturday, the 3rd July, 1880, was 20·9 per 1,000 of estimated population. This rate is 1·7 above that for the corresponding week of last year, and 0·4 above that for the previous week of the present year. The lowest mortality was recorded in Greenock, viz., 14·4 per 1,000, and the highest in Paisley, 36·1 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·0 per 1,000, being an increase of 0·2 over last week, but the number of deaths from the different diseases was very little changed. Acute diseases of the chest caused 91 deaths, being 12 more than the number recorded for the previous week.

FACULTY OF PHYSICIANS AND SURGEONS.—At their monthly meeting, held on the 5th inst., contrary to the opinion expressed in our last impression, the Faculty cordially agreed to invite the British Medical Association to Glasgow for their next meeting.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.—The Medical Board of this hospital have appointed James Limout, M.A., B.Sc., and L. Ralston Huxtable, house surgeons for the quarter beginning on the 1st proximo, in succession to Thomas Caverhill, M.D., and Russell E. Wood, M.B., C.M. Dr. J. Halliday Croom will succeed Dr. Keiller as medical officer on duty on 1st August.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, NORTH BRITISH BRANCH.—The quarterly preliminary examination of the Society for Edinburgh and district, took place in Edinburgh on the 6th inst., when twenty-seven candidates presented themselves for examination, the largest number that has appeared in Edinburgh. The examination is conducted by the College of Preceptors, London.

AYR—A NEW HOSPITAL.—A new hospital is to be erected in Ayr, and the work is to be commenced immediately. The length of the building is to be 240 feet, and the depth 120 feet, with a central tower of 65 feet high. The site of the new institution is a little beyond the Kyle Combination Poorhouse. Mr. Murdoch, Ayr, is to be architect.

FORFARSHIRE—MEDICAL ASSOCIATION.—The twenty-second annual meeting of this Association was held in Arbroath, on the 8th inst. J. S. Crichton, M.D., President, in the chair. Dr. Key, Montrose, was elected President for the ensuing year; Dr. Johnstone, of Kair, and Dr. Miller, Dundee, Vice-Presidents; Dr. Sinclair, Dundee, Secretary; and Dr. MacEwan, Dundee, Treasurer. A motion to consider the whole subject of medical fees was agreed to, a report to be given in at the next annual meeting. Dr. Sinclair addressed the meeting on the Vaccination Acts Amendment Bill, and a motion that this Bill should not be permitted to become law was agreed to. The President read a paper on "Coal-Gas Poisoning," and Dr. Miller "On the Hygiene of the Infectious Fevers." The members and their guests dined in the White Hart Hotel in the afternoon.

AIRDRIE.—Dr. Rankin has been appointed Medical Officer and Police Surgeon for the Burgh.

ST. ANDREWS MEMORIAL COTTAGE HOSPITAL.—A union has been effected by the Committee of the Adamson and Bell Memorial and the Managers of the Douglas Cottage Hospital, and henceforth the institution will bear the name of the "Memorial Cottage Hospital." In the annual report it is trusted that the greater publicity and permanence conferred on the institution by the new arrangement may secure for it the increase of public support and sympathy which the more expensive house and ampler accommodation call for.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 3rd inst., the rate of mortality in Edinburgh was 22 per 1,000. No death was reported from scarlet fever, small-pox, nor diphtheria.

Correspondence.

CHEAP DISPENSARIES.—No. II.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—One of the most, if not the most, important of the sources of the existing abuses is the exaggerated importance which is attached by medical men to individual fees. It is nothing that a man may receive a fair income for a moderate amount of work if he is not paid in a certain way. It would be better that he should see one patient for £1 1s. and ninety-nine others as a charity than that one hundred should see him for 1s. apiece. In the country, where charities are not within the reach of every one, and the poor must be attended, the difficulty has to be met, but it is effected so as to obscure the bugbear of small fees as much as possible by making people pay 1d. or 2d. a week, or some small sum yearly, and many a man who has done this all his life would positively feel he was lowered in the social scale by accepting what would be really far better remuneration in the shape of a fee. Based upon the same intangible prejudices, innumerable anomalies have come into existence. Here is another instance. A country practitioner will commonly draw a tooth for 1s., an operation which is at any rate disagreeable and troublesome to most men, and which is hardly made more attractive by the reflection that it might possibly have been done almost as well by the village blacksmith, but he would hesitate to give the same man a bottle of medicine, even though it cost almost nothing in value or trouble, for the same money. Instances of this kind might be multiplied, but space forbids.

The intense prejudice which is specially directed against small fees paid at the time is certainly illogical enough, and seems to be due to the fact that the smallness of the transaction is brought too prominently forward, and is thus a serious blow to a befitting sense of professional dignity, and any method which keeps this objectionable feature in the background by separating the payment from the thing paid for is to be welcomed. However, it is probable that a dignity which depends on such sentimental distinctions as these will in time prove amenable to considerations of obvious pecuniary advantage, if they can once be clearly apprehended.

More practical, and perhaps more general, is the feeling that a reduction of fees will reduce indefinitely the aggregate of medical remuneration.

Well, I suppose a profession has a right to muzzle competition if it can; but it is perfectly clear that there is only one way to do this, *i.e.*, by limiting the number of its members. Nothing short of this can possibly have any real influence on competition. As long as the gateways of medicine are barred only by a certain standard of education, with the expenditure of time and money which this involves, so long the remuneration to be obtained in the profession cannot vary very much from what will buy an equivalent of these commodities in other walks of life, and this balance is not affected by the measure of individual fees. Some prominence has been given to a statement of J. S. Mill, to the effect that competition amongst professional men exists in the number of competitors rather than in the amount of the fees. But the result is precisely the same in either case. Let medical fees be raised by the most loyal co-operation throughout the profession; the increase in the numbers, who will at once compete for them, will soon restore the equilibrium, and if small fees, or any other cause should bring it about that educated talent found a better market elsewhere, how long would disinterested philanthropy, or any other motive, suffice to attract it to the ranks of medicine? On the other hand, if a high degree of education should be divorced from the profession by inadequate remuneration, a portion of the public who consider education of some importance, would bid high enough to recall it; in others words, if educated men were to become more scarce, those remaining would be more in demand. This simple fact hardly requires demonstration, that as long as a profession is practically open to every one who chooses to enter it, the question of its remuneration is as much beyond the reach of arbitrary regulation as is the hydrostatic law by which fluid raised in a closed tube finds the general level as soon as an opening is made.

A charge of want of public spirit is often made against all poorly-paid members of the profession. Public spirit is a great virtue, but no amount of preaching will make it rank in the popular mind before the necessaries of life. These suicidal persons would answer that they got the best terms they could; if they had not taken them plenty of others would, and when one considers that at the Scotch schools plenty of men earn enough as brick-layers or farm-labourers in the summer to pay for their classes in winter, and get them a diploma, it is not clear that even these despised appointments are a bad alternative for the plough or the trowel.

To turn now to the alleged impossibility of small fees being remunerative, and considering this to be principally the concern of those who accept them, I should have been disposed to leave it alone, had not the implication of fraud made it necessary to deal with this subject, and to point out the mis-statements of facts on which such assertions depend.

It is impossible to enter into this subject fully, but let anyone select at random 100 mixtures from the Hospital Pharmacopœia, and calculate the cost at wholesale prices of a quantity of medicine, sufficient to last a patient two days. In spite of a good many ingredients not absolutely necessary, such as spirit, syrups, &c., the average cost will not exceed one penny, or less than 20 per cent., on such a small sum as 6d. A much smaller number of patients than those who are seen daily at many hospitals would yield a very fair profit after deducting 20 per cent. to pay for their medicine.

The whole idea of small ready money payments for skilled advice is utterly repulsive to the opponents of the dispensary system, contending that advice cannot be sub-divided or measured, that it is an absolutely constant quantity, representing the whole skill of him who gives it. It follows to them that the medical man must give, in every respect, the same identical article, whether he is paid 6d. or £1 1s. for it, and if the one is fair, how grossly inadequate is the other!

But if skill does not admit of division, time does; and it is the skilled labourer's time, which is the fairest measure of his remuneration. Suppose one man has to visit two patients who pay 5s. each, and the two visits take an hour, and under other circumstances he is able to see, in the same time, 20 patients who pay him only 6d. a-piece. According to the first line of argument, everyone of the 20 rob him of 4s. 6d., for they receive the same identical article as the other two.

The essence of the whole dispensary system lies in the consideration that a medical man, like any other, may justly afford to dispose of a few minutes of his time for less money than would remunerate him for half-an-hour, and in an endeavour to enable him by some method to give a short space of his time to those who could not afford to pay for more, with profit to himself.

This is the principle which must underlie clubs, or provident dispensaries, or any other method which aims at enabling the poorer classes to pay for advice, and unless it is recognised nothing is left but the monstrous alternative to pauperise everyone who cannot pay 5s. every time he wants to see a doctor.

Moreover, this end is attained by mutual concession; it is not all on the doctor's side. If the patient pays a small sum the attention he receives is curtailed in proportion. He sacrifices his convenience, and, in fact, resigns all the luxuries of professional attendance; and when this is taken into account it is probable that he pays as well for what he receives as his more opulent neighbour, and is as independent of charity or favour.

This case may not inaptly be compared to that of a third-class traveller, who pays only for the essential part of the transaction, viz., the journey, but dispenses with all unneces-

sary luxuries; and the parallel is true, to a further extent, which might allay the rather groundless fears of those practitioners who see, in a movement of this kind, nothing but an attempt to cut them out. For just as some people travel third-class, who are not obliged to do so by want of means, so occasionally patients who can afford more will go to a cheap dispensary. But that any large numbers will accept the discomfort, inconvenience, and above all, the suspicion of poverty which is implied, is no more probable than that all the upper classes will take to travelling third-class.

Your obedient servant,

A. B.

Medico-Parliamentary.

HOUSE OF COMMONS.—FRIDAY JULY 9TH.

THE CONTAGIOUS DISEASES ACTS.

Mr. CHILDERS moved the appointment of the Select Committee on these Acts.——Mr. C. BENTINCK expressed the opinion, that having regard to the scope of the inquiry that was proposed to be taken, it would be useless to appoint the Committee at this time of the session.——Mr. CHILDERS said that the delay in the appointment of the Committee was due to the difficulty of finding gentlemen who would take part in this disagreeable inquiry.——Mr. PULESTON thought that it would be useless to appoint the Committee this session.

The discussion was adjourned.

MONDAY, JULY 12TH.

THE SUPPLY OF VACCINE.

Mr. DODSON, in reply to Mr. Hastings, said he could not give a definite answer to the query as to when the National Vaccine Establishment would begin to supply calf vaccine. The Local Government Board were making inquiries to ascertain what would be the best arrangement in order to secure an adequate and constant supply of the lymph. There was every desire to push the matter on, but some further time must elapse before the Board were in a position to commence the requisite supply.

FAMINE FEVER IN IRELAND.

Mr. FORSTER, in reply to Mr. Power, said that, so far as he could ascertain, the outbreak of fever in Ireland was chiefly in the Poor-law Union of Swinford, where forty-one persons were suffering from fever in hospital. Some additional cases were reported in the last few days, but he had reason to believe that the disease was on the decline. A chief cause of it was attributed to the overcrowded and generally unsanitary condition of the cabins.

Presentation to Dr. Norman Kerr.—In acknowledgment of the disinterested and devoted services of Dr. Kerr in the cause of temperance, a presentation took place in the rooms of the Medical Society of London on Wednesday last. The testimonial consisted of an illuminated address, portraits of Dr. and Mrs. Kerr, and a handsome carriage and set of harness. Dr. Richardson, F.R.S., was asked to undertake the graceful task of presentation on behalf of the subscribers, among whom were several members of the medical profession. In acknowledging the honour done him, Dr. Kerr made a most felicitous speech, and the proceedings throughout were of the most cordial character.

Queen's University in Ireland.—At a meeting of this University, held on Monday, June 21, the following degrees and diplomas were conferred :—

Degree of Doctor in Medicine.—John Howard Battye, of Queen's College, Belfast; George J. Coates, of Queen's College, Cork; John J. Dinnis, of Queen's College, Cork; Arthur Hickman, of Queen's College, Galway; Edward Horan, of Queen's College, Cork; Daniel Lehane, of Queen's College, Cork; William J. Matthews, of Queen's College, Belfast; William T. Mullally, of Queen's College, Galway; Patrick Mullane, of Queen's College, Cork; James Mullin, of Queen's College, Galway; John F. L. Mullin, of Queen's College, Galway: Menus W. O'Keefe, of Queen's College, Cork; Samuel Townsend, of Queen's College, Cork.

Degree of Master in Surgery.—Dr. Charles Hall, of Queen's College, Belfast; Dr. John Horsford, of Queen's College, Cork; Dr. Charles Frederick Knight, of Queen's College, Cork; Dr. John Martin, of Queen's College, Galway; Dr. William Smyth, of Queen's College, Belfast; Dr. William Stokes, of Queen's College, Galway; Dr. John Wilson, of Queen's Colleges, Belfast and Cork; Dr. Ralph Worrall, of Queen's College, Belfast; George G. Coates, of Queen's College, Cork; John J. Dinnis, of Queen's College, Cork; P. Mullane, of Queen's College, Cork; Menus W. O'Keefe, of Queen's College, Cork; Samuel Townsend, of Queen's College, Cork.

Diploma in Midwifery.—Dr. William Stokes, of Queen's College, Galway; George J. Coates, of Queen's College, Cork; Patrick Mullane, of Queen's College, Cork; Menus W. O'Keefe, of Queen's College, Cork.

NOTICES TO CORRESPONDENTS.

SPECIAL NOTICE TO CORRESPONDENTS.—In consequence of the Index appearing in the present number, together with the proceedings of the General Medical Council, we are compelled to hold over several original communications, letters, reviews, and notices.

"SPECIAL REPORTS ON MINERAL WATERS."—The continuation of this series of analytical and therapeutical Reports is unavoidably held over for want of space.

WHY DOES A WOMAN LOOK OLD SOONER THAN A MAN?—Observing an advertisement with this heading in an American medical exchange for June we naturally paused, in the hope of gaining information. The advertiser had the best of it: in a two-column advertisement he demonstrated conclusively that if women used nothing but "Frank Siddal's Soap" the matter would be at once settled to the satisfaction of the female mind. In proof of his case, he cites testimonials from three American physicians—Drs. Eagleton, Sargent, and Stradley, all of whom have used it with beneficial effects. We presume this trio are lady-doctors, although we notice they boast of male prefixes. Verily "while there's life there's soap."

VACANCIES.

Bristol, University College.—Registrar and Secretary. Salary, £400. Full information obtained on application to the Secretary.

Gort Union, Ardrahan Dispensary.—Medical Officer. Salary, £140, with fees, and £10 as Medical Officer of Health. Election, July 29.

Hertford General Infirmary.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Chairman before July 24.

Manchester, Owens College.—Lectureship in Practical Surgery. Information from the Dean of the School. (See Advt.)

North Devon Infirmary.—House Surgeon. Salary, £100, with board. Applications to the House Committee, under cover to the Secretary, at Barnstaple, by July 17.

North Staffordshire Infirmary.—House Physician. Salary commencing at £100, with board, &c. Applications to the Secretary, Hartshill, Staffs, before July 27

Paris—Hertford British Hospital.—Resident Clinical Assistant. Salary, 100 francs per month, with board. Applications, with testimonials, to be addressed to the Physician at the Hospital, Neuilly, Paris, before July 20.

Parsonstown Union, Kinnetty Dispensary.—Medical Officer. Salary, £120, with fees, and £20 as Medical Officer of Health. Election, July 27.

APPOINTMENTS.

BROWN, Mr. J. M., Demonstrator of Anatomy in the Owens College, Manchester.

BRYAN, C. F., M.R.C.S.E., Medical Officer to the Workhouse of the Leicester Union.

DICKINSON, Mr. T. V., House Physician to St. George's Hospital.

FISHER, Mr. F. C., House Surgeon to St. George's Hospital.

GLAISTER, J., M.B., C.M., a Resident Medical Officer to the Leeds Public Dispensary.

HOLLAND, J. C., L.K.Q.C.P.I., Medical Officer to the Dungarvan Workhouse.

HOLMES, D., M.B., L.R.C.S.E., Medical Officer to the Aston Branch of the General Dispensary, Birmingham.

HOYLE, W. E., M.R.C.S.E., House Surgeon to the Whitehaven and West Cumberland Infirmary and Fever Hospital.

INNES, H. D., M.R.C.S.E., Junior House Surgeon to the Huddersfield Infirmary.

LEWIS, C. J., M.R.C.S.E., L.R.C.P.L., Resident Surgeon at the General Dispensary, Birmingham.

SHAPLEY, F., M.R.C.S.E., Assistant Medical Officer to the Wonford House Hospital for the Insane, Exeter.

STRAHAN, S. A. K., M.D., Assistant Medical Officer of the East Riding Asylum.

TAYLOR, F., M.R.C.S.E., House Surgeon to the Teignmouth, Dawlish, and Newton Infirmary.

WALFORD, E., M.R.C.S.E., Medical Officer of Health for the Urban Sanitary District of Ramsgate.

NAVY MEDICAL DEPARTMENT.—Staff-Surgeon D. McNab Johnston, M.D., has been promoted to the rank of Fleet Surgeon in her Majesty's Fleet, with seniority of the 4th inst.

Births.

HOPKINS.—July 7, at Kingswear, Sutton, Surrey, the wife of Surgeon-Major Nathaniel Hopkins, I.M.D., of a daughter.

PARSONS.—July 6, at South Norwood, the wife of H. Franklin Parsons, M.D., of the Local Government Board, of a daughter.

WEBB.—July 7, at Gibraltar, the wife of Brigade-Surgeon W. M. Webb, A.M.D., of a son.

Deaths.

BENNETT.—July 2, at Hornsey, Middlesex, Charles Frederick Bennett, M.D., late of Lymm, Cheshire, aged 55.

DOVE.—July 5, at Stowmarket, Suffolk, Harry Dove, M.R.C.S.E., aged 30.

LANIGAN.—At Ballymahon, co. Longford, F. J. D. Lanigan, M.R.C.S.E.

NOLAN.—At Ballina, co. Mayo, J. J. Nolan, L.R.C.S.I.

PALGRAVE.—July 2, at Kilburn, John Henry Palgrave, retired surgeon, Bengal Army, aged 78.

THE PHYSIOLOGIST IN THE HOUSEHOLD. (a)

By J. MILNER FOTHERGILL, M.D.

Part I.—Adolescence.

There is one grave and serious omission in even the most advanced of our educational systems, and that is, the child is taught nothing about itself. What its relations to its surroundings as an organism are, it is never taught. It is true it is now taught elementary physiology, and is told of what textures its body is built; how its circulatory system is developed; what are the different portions of the brain; what the changes which go on in digestion and assimilation; how certain albuminoid bodies are converted into tissues; how the hydrogen and carbon elements of our food are oxidised and converted into body heat and force. It is also taught the history of various nations, and thereby is instructed how masses of human beings have acted under certain conditions in the past; but about itself as an organism, as a social unit, it is left absolutely uninformed. It may be largely endowed with strongly-marked inherited traits which will profoundly influence its conduct in life: never a syllable is whispered to it of the importance of recognising this, and of the utility of striving to cultivate itself accordingly. Even the lower or animal nature is never discussed, and the child is allowed to pass away from the neuter *it*, to the masculine *he* and the feminine *she*, without one word being said to it as to the momentous changes involved in the birth of sex. It is allowed to ascertain for itself and by itself what its nature is. The child has no power to project its consciousness forward, to realise in its imagination what the experience of its elders can be and consequently it cannot foresee what will be the unavoidable results of a course of conduct to which it may be tempted with a force to it irresistible. It knows nothing! How can it know anything of those social safeguards over conventional habits and usages which have been established to protect the individual in times of peril and temptation? It can recognise nothing of their utility; probably they strike it as conventional absurdities, for the eye can only see what it has learnt to see. The child cannot read betwixt the lines and realise the solid reasons which underlie many of our social arrangements. The child possesses no consciousness as to what is involved in the experience of the adult. It does possess, however, blind impulses, instinctive promptings, which it recognises, and which it will follow determinedly. Nothing is ever said to it about such possessions; it is left to itself to seek its own experience; it is left alone, single-handed, without a word of caution as to the acquirement of its own knowledge, often at a terribly expensive cost. It pursues its course blindly, because no one attempts to open its eyes as to its instinctive promptings. It cannot see those unavoidable consequences of its actions, which are veiled from its vision; but which are so terribly vivid to its elders. It errs as much from ignorance as from vice. Knowledge it certainly gains for itself; and sadly, too frequently when that knowledge is acquired, an imperfect existence, a battered wreck, a darkly-shaded soul, are all that is left.

There is nowhere for the child to turn to get advice or counsel on these matters, even if it should perceive the

(a) This essay was written at the expressed desire of several friends, parents and teachers among others. The subject is a most delicate and difficult one; I have therefore asked the editor of *The Medical Press and Circular* to permit it to appear in his columns previous to its appearance in pamphlet form; to this he has kindly consented. By this means it will be brought before the profession, and I trust those who read it will give me their impressions, whether of approval or disapproval (as much the latter as the former will be welcome for my guidance). If the bulk of opinion be favourable then the subject may be pursued in another essay. The phraseology of the pamphlet is preserved here; this is obvious, but it is as well to have an understanding about it. It has passed much private criticism before being made public; still further criticism is desirable. The crying necessity for some such work is generally acknowledged; but how to approach the subject in a manner at once instructive yet decent is felt to be a very difficult matter. The growth of physiology as a subject of school teaching is rendering it possible to approach the matter in an unobjectionable manner, if the execution of the design is at all proportionate to the good intentions which originate it. The question is not, "Is now the time for such an essay?" but "Is the thing itself practicable? and if so, is this essay likely to do some good and no evil?" The verdict must not be anticipated as very necessarily favourable; it must be awaited patiently.

necessity thereof. There is none upon whom falls the responsibility of informing children on such subjects ; in our present social arrangements we possess no one whose duty it is to tell the child about itself, to explain to it what its nature is. Its parents are too commonly unequal to the task, and even those who do recognise the tremendous urgency for some such education, shrink from the difficulties inherent in the task. Frequently they earnestly wish for some literature which they could put into the hands of their children which would tell them what they themselves are unable to tell. It is not the duty of the schoolmaster or schoolmistress, who, however, often recognise the imperative necessity for some such guidance for children, even when the parents' eyes are not open to the necessity. It cannot be delegated to the family doctor ; certainly it cannot be devolved upon the clergyman—at least in the Protestant countries. As matters stand at the present, the instruction must take the form of a written work. Such is the crying necessity for such a work, that the attempt is here made to write one. Imperfect, from the nature of things it must be ; defective, it cannot help but be ; and the reader, adult or child, must be lenient to the writer in the face of an attempt novel in design, but with all the difficulties which surround the subject distinctly borne in mind. It will be essayed here in homely garb and simple language, to tell the child something about itself, as it is, and as it will be ; and the attempt must command the sympathies of those who have at heart the interest of their fellow beings. If any parent or teacher can find in this pamphlet their way a little cleared towards the physical education of their children and pupils—a matter the importance of which is now clearly recognised—the writer will be amply rewarded.

In the first place, a child must recognise the fact that he possesses a greater and a lesser inheritance. The first is his heritage as an organised being, an animal in fact, with an animal's cravings and instincts. The lesser heritage is that of his family peculiarities. He must be taught to realise that in the mind as well as in the body he will bear a marked resemblance to his near relatives. What they have been for good or evil he will tend to be. Such as they are he will be. Individual differences slowly develop, and only manifest themselves in time above the characteristics of the animal and of the family or race. Were this sufficiently recognised, a child, in the plastic period of youth, when it can readily be moulded, might have it pointed out to it what to strive after, what to avoid, what tendencies it had which could be trained for its benefit, it could be led away from that part of its inherited peculiarities which is undesirable ; it could be guided in the development of what is desirable. It might have pointed out to it those family traits which will render it lovely and good ; and further, it might be trained away from those family tendencies which will render it unlovable, but which it recognises only when past the plastic stage ; and when too late, it is " marble to retain " the impressions formed or made.

Then it must be taught to know that it is a child, and that childish things are not unbecoming in a child at the appropriate age. In the idiot, and the feeble-minded, the characteristics of childhood remain ; the child lacks the power to outgrow them. The natural emulous rivalry of children educates them, without the necessity for much attention, out of this danger. But there exists another danger much more fraught with peril, and that is, precocity. This is often fostered by parents, loving but imprudent, who pride themselves upon the brightness of their child. Instead of being something to admire, really it is the thing of all others which is not to be desired. Brilliant children rarely attain manhood ; their delicate organisations cannot resist the blow of scarlatina, measles, or hydrocephalus (water-in-the-head). One of our profoundest thinkers taught that children of defective constitution resembled in the development of the bones, and especially the skull, races lower than the one to which they belong. They are " infantile or of a lower ethnic form " (ethnic here meaning racial, of or belonging to, a race). He says of them mentally, " mind precocious, but mental powers imperfect, or if good, soon exhausted." The precocious quickness of some children, however much it may seem desirable and to be coveted, is not, in reality, a thing to be desired. This should be impressed very clearly on the minds of children, even upon the mind of the precocious, in order that it may not force itself forward. It should be encouraged to desist from its mental toil, and its growth, its physique, should receive sedulous care.

Indeed, it would be well to take the direction indicated by the soliloquiser in Locksley Hall, in speaking of what he would like to see his children :—

" Iron-jointed supple-sinewed, they shall dive and they shall run,
Catch the wild goat by the hair, and hurl their lances in the sun ;
Whistle back the parrot's call, and leap the rainbows of the brooks,
Not with blinded eyesight poring over miserable books."

We have said before that childishness remaining late indicates the imperfect or feeble in mind : but a distinction exists betwixt childish children and slow children. That charming writer, Oliver Wendell Holmes, once discoursed with subtle power upon " late pears." He said, " Men often remind me of pears in their way of coming to maturity. Some are ripe at twenty, like human jargonelles, and must be made the most of, for their day is soon over. Some come into their perfect condition late, like the autumn kinds, and these last better than the summer fruit ; and some that, like the winter helis, have been hard and uninviting, until all the rest have had the season, get their glow and perfume long after the frost and snow have done their worst with the orchards. Beware of rash criticisms ; the rough and stringent fruit you condemn may be an autumn or a winter pear, and that which you picked up beneath the same bough in August may have been only its worm-eaten windfalls."

Now this is very true ; and the big dull lads of the school-room and play-ground are not always dunces ; they are often really " late pears," and will develop slowly, and in time, into able men of strong intellectual power. The prospects of the precocious child and the " late pear " are very unlike, and infinitely in favour of the latter. To some extent the same holds good of girls, who resemble —I beg the sex's forgiveness for my freedom—rather the precocious boy than the late pear.

The nervous organisation of woman favours early development, and age for age girls are ahead of boys, just as is their physical stature ; but in mind and body alike their growth does not go on so long as is the case with boys : they reach their utmost development earlier than boys, but the male intellect outstrips that of the female at last.

Early maturity, which is intimately linked with precocity, is most undesirable ; it indicates a low standard of development. Not only does this hold good of the individual, but it is true of the mass. Town children attain their full stature, according to Quetelet, at an earlier period than country children ; but the average height of country children is above that of town children. The countryman grows more slowly than the townsman, but then he goes on growing long after the time when growth has ceased in the townsman : so it is intellectually. The child brought up in towns, and especially London, lives in a perpetual whirl of excitement compared to the life of a child reared in the country. The one is living his life, spending his energy ; while the other is storing his force. The one is eating his cake, the other is keeping his. At fifteen the little Cockney is far in advance of the country child, who looks a heavy lout by his side, in all knowledge of the world ; but in the race of life the Cockney, though still advancing, ceases his development comparatively early, while the countryman is going steadily on. At twenty-five the Cockney is still a head someway ; but at thirty-five the Cockney has lost the lead,

and the countryman is considerably ahead; at forty-five the Cockney is not in sight, and is hopelessly behind. What is true of the Cockney and the country-bred child *en masse*, is also true of the individual; and though bright children are undoubtedly pleasant to associate with, the slow child frequently makes the abler man, when middle age is reached. With some children, then, it is desirable to hold them back; while with others, stimulants to exertion are required. But the sharp child must not hold the slow child too cheap, especially if the slow child belongs to a stock endowed with brains. Of course families vary materially, some are much brighter than others. The child of a dull stock will probably be dull all along the line of life. The child belonging to a bright sprightly family will also be of quick parts when young: but that does not materially affect the truth of the argument, viz., that early development is antagonistic and opposed to final development. It is notorious that the races for two-year olds are exercising a most pernicious influence upon the stamina of our race horses. A horse which has been well fed, and not been put to any work till its full growth is attained at six years old, is a better horse, can do more, and will last a great deal longer than a horse of equal qualities, by descent and otherwise, which has been put to work betwixt the age of three and four. So it is with men: the full growth should be attained before the intellect is severely exercised for the full development of it in maturity. It is the *mens sana* in the *corpore sano*;—precocity counts off so much from the ultimate and potential development.

At this point something may be said as to the relations of growth to education, which formed the subject of a lecture by the writer to "The London Schoolmistresses' Association" in November, 1877. It is quite clear, to start with, that if a child be put to severe study, the demand upon it will tell upon its body development and physique. This is well seen in the slight figure of the women of the New England States, where the educational course is very severe. What will be the effect of the present insistance upon competitive examination on the physique of the next generation remains to be seen. Education must necessarily be carried on during the period of growth; that is inevitable. The battle of life is fought with the brain now, and not so much with muscles, thews and sinews, as of yore; and the brain must be trained, come what may to the body. But growth is not a steady increase upwards, like an inclined plane; it consists of periods of active growth, and then an interval of quiescence, like that of trees and other vegetable growths, which shoot in spring; only the periods of growth in children are less rhythmical and more irregular. This is an important fact both for teachers and children. During the period of active growth the bones are elongating, and the muscles have to keep pace with them. The blood is drawn to the growing parts, and away from the brain, which consequently is starved, and thereby rendered inactive. The child is comparatively stupid and lacking in intelligence, its ordinary tasks become a toil to it, it feels it cannot cope with them as is its wont. Perhaps it becomes depressed thereby and is unhappy, more commonly it is punished for idleness or carelessness. But when the period of active growth is over, then the child brightens up, struggles successfully with its lessons, and quickly regains the lost ground. Sometimes the period of active growth is brief, at other times it is prolonged. At times the child is utterly incapacitated from pursuing its studies, and has to be sent to the sea-side. This subject has not received the attention it merits, and which it will before long command. It is cruelty, and cruelty of a very objectionable character, to compel a child to pursue its studies when actively growing, to say nothing of punishments inflicted where blows would be preferable to tasks, and impositions which only increase the demand upon the over-taxed brain. Such irregular "growing fits" are a source of much disturbance to teachers, and if a class would all grow actively at the same time it would be great convenience, but this is as unattainable as regulation of the weather.

(*To be continued.*)

SUNSTROKE AS I HAVE SEEN IT IN INDIA.

By Surgeon-Major WILLIAM CURRAN,
Army Medical Department.

(*Concluded from page 6.*)

If, now, looking more closely into the question with the aid of the several considerations set forth within, we ask ourselves, what is sunstroke? we will, I think, have no difficulty in arriving at the conclusion that it is a neurosis of cerebral origin, the result of a depressed, nay, an actually paralysed condition of the nerves of animal life. Many circumstances concur in leading us to adopt this view of its pathology, and the cerebral congestion described above implies, I think, as much. The phenomena of the circulation within the cranium, as explained by Burrows and others, imply also a very close relationship between its nervous and vascular contents; and several of the witnesses who appeared before the Royal Commission on vivisection, assumed as proved the belief that "the vaso-motor nerves were the regulating nerves of the blood-vessels." (61) I have myself been often struck while watching several of the seizures noted above, with the likeness they bear to cases of concussion, or rather compression, of the brain, and one gentleman, who recovered from what threatened to be a serious attack, assured me that his earlier sensations were very similar to those ascribed by Byron to Mazeppa. (62)

However that may be, heat-apoplexy seems to me to be the properest designation for the condition that kills in this disease, for there is no doubt that it is of an apoplectic character, and that the pale face, the flabby, flaccid cheek, and the puffy, flapping expiration, that so often usher in death in this disorder, are its direct and legitimate offspring. Nor are the local antecedents of these phenomena as different as might be supposed at first sight. We need not, indeed, have in sunstroke all those changes in the vascular network of the brain (63) which are usually found in connection with apoplexy or compression. Neither need we assume, on the other hand, an actual escape of serum or of blood within its cavity in either of them, but we must, I think, assume a condition of extreme nervous depression in all three; and this is the cause and the explanation, in my humble opinion, of all the changes that take place in the head as well as in the chest in this malady.

The experiments of Brown-Séquard, John Reid, and Weber appear to me to support this view, but a detailed application of these to our thesis would take us too far a-field, and they must be as familiar to my readers as they are to me. They all go to show, as I apprehend them or their bearing on this point, that death invariably occurs in heat-apoplexy through paralysis or shock of the vaso-motor nervous system; and I have a fixed impression that the remora or engorgement of the lungs is subsidiary to or consequent on this shock or paralysis. The facial or other muscular twitchings that are so common in the earlier stages of this seizure, as well as the groping of or picking at the throat and bed-clothes that sometimes, though rarely, follow on its prolongation, appear to me to indicate a similar starting-point; and coma and convulsions, the two commonest modes of dying in sunstroke, have ever been associated with a nerve irritation or paralysis. So also have, though less certainly, been the accumulation of mucus in the bronchi, and the tendency of the pulmonary tissue itself to secondary implication, while the cardiac structures evince no such disposition, as well as the difficulty of swallowing, which are frequently encountered in sunstroke, are more suggestive of a cephalic than of a cardiac sympathy.

Whether this is an adequate explanation of the

phenomena or not I am unable to prove, but it is the one that most commends itself to my mind, and I have given the matter a great deal of thought and consideration. It has, at least, the merit of simplifying the question, or rather of dispensing with that somewhat far-fetched hypothesis, cardiac syncope—a condition that rarely obtains under the circumstances here contemplated or among the classes with whom I have been most conversant—and the post-mortem appearances of the heart lend it no support at all. On the contrary, they rather tend to show that this organ is much less implicated in such a catastrophe than it ought to be, for its ventricles rarely contain any more foreign or obnoxious material than a little semi-coagulated dark blood, and I do not remember ever seeing any evidence of a recent endocardial or other inflammation in it. Organised fibrinous clots are certainly not common in them, and its tumultuous or uncertain action may be easily explained by its relationship to, or dependence on, the failing power of the pneumo-gastric or the embarrassed and labouring lungs. The temperature of the brain is, as I have just observed, also higher after death than is that of either the chest or the abdomen, but this may be due, in part at least, to the greater elevation or exposure of the former, and I now regret very much that I did not pay more attention to this very interesting, though somewhat ghastly part of the investigation on the spot.

Believing, then, that the phenomena of sunstroke are explicable through the assumption of a more or less complete or temporary paralysis of the vaso-motor system, and that its mainly inducing factor is the exhaustion that is produced by long-continued or excessive heat, (64) I come to discuss its treatment, in so far, at least, as that has not been done already, and the particulars given in the tables and elsewhere will enable us to dispense with details in this direction, which might be otherwise necessary. Premising that I have never been able to connect the prevalence of this disorder with malaria, or, indeed, with the presence of electricity in excess in the air, though it is, it must be confessed, commoner during the state of atmospheric tension which precedes a thunder-storm than at other times, I will only add that its fatality is greater, according to my observation, at night than during the day, and under a cloudy than it is under a clear sky.

However that may be, and these are points which can only be determined by a widely extended series of meteorological observations, the treatment that has proved most successful in my hands has been a combination of the hot-bath and of the cold-douche; the body being immersed up to the neck, in the former, while access to both is cut off by a properly adapted waterproof sheet, the cold douche is to be steadily and vigorously plied to the head and neck, till the temperature of these is reduced to its normal level, or if that be not possible, till respiration or sensibility becomes re-established. With this view the body should be so raised from time to time, as that the chest, and even the abdomen, may be subjected to the influence of the cold spray from a height of some three to six feet above the sufferer; and, meantime, leeches should be applied in such numbers as will take to the temples and jugular fossæ. All this may be done in the climate of Hindostan in the open air, or in a verandah, for the patient requires the fullest access he can get to the air, and I assume that previous to, or coincidentally with the above, the bowels have been acted on through the mouth or the anus. If the patient can swallow, calomel and croton oil should be exhibited through the former, while a turpentine and salt enema is the best for the latter, and I have never found any benefit, at least, not any very perceptible benefit, from the application of rubefacients or counter-irritants to the abdomen or other parts of the body.

As regards the other measures employed or recommended in this disease, such as the mud-bath and galvanism, the hypodermic injection of quinine, artificial respiration, and, finally, the application of heat to the head, &c., I have not much to say. Neither, indeed, does it appear that they have been used with sufficient frequency and success to justify any authentic inference being drawn as to their efficacy, and some of them are, at least, not always attainable. I have never, myself, seen the mud-bath used, but I have heard of instances in which it saved life in the field during the mutiny, and galvanism has never appeared to me to influence the heart favourably during the paroxysm, while it might prove injurious after the latter had spent its force. The cases quoted above, as well as those that have been described to me by others, satisfy me, and will, I trust, satisfy the reader, if he is not content with my oft-repeated assurance to this effect, that the value of quinine injected subcutaneously in the treatment of this malady has been grossly exaggerated.

Anyhow, it has utterly failed in my hands, and so marked has this failure been that I have often thought the cases that came under my notice either differed in type from those recorded by the advocates of this drug, or that there was a mistake in diagnosis somewhere. In no other way can I account for the extraordinary discrepancy referred to, and as to artificial respiration, which did certainly prolong the struggle for life for a few minutes in one or two of my cases, I can only here say that it will never succeed, in my opinion, in saving it, in any typical or aggravated instance. Mr. Barnard, of the Indian army, alleges, however, that he has succeeded in some cases with it, and it is, at least, quite worthy of further trial. Those, however, who believe with me that the *fons et origo mali* lies within the cranium rather than inside the thorax, will scarcely be convinced by this gentleman's reasoning; and the circulatory suspension, which he wishes to restore by its agency, depends, as I have endeavoured to show, on conditions which do not admit of being influenced by this process.

Touching the strange belief that the proper cure of sunstroke is the immediate application of substances capable of absorbing redundant heat from the system rapidly, and by counter-irritation, or otherwise attracting a portion of it to some organ not so delicately related to the centre of vital force as the brain is, all that need be said is that this would undoubtedly be a good—possibly the best—course, did we know of any such substances as are here contemplated. But we do not, unfortunately, and the suggestion of hot bricks "to form a pillow for his head and the back of his neck," would simply send our poor patient prematurely, and without any chance or alternative, to his grave. Vague, high-sounding phrases of this kind are, notwithstanding their plausibility, much to be deprecated in all walks, but especially in those of medicine, and we may reasonably question the capacity, if not, indeed, the sanity, of a man who presumes to define *coup-de-soleil*, at this hour of the day, as "a species of heat-bite strictly analogous to frost-bite, and subject to the same curative law. It is caused by heat, and should be cured by heat." (*a*) There is no more analogy between the two than there is between Macedon and Monmouth, or between the Goodwin Sands and Tenterden Steeple, and whatever credit or value the *similia similibus* doctrine may have achieved in the cooler West, it is altogether out of court in the burning East. There we must strike with the sledge-hammer rather than with the gloved hand. *Principiis obsta, sero medicina paratur*, should be our motto and our guide, and in no disease is its lesson so valuable as it is in the disease with which we have been so long conversing together in these pages.

So much for sunstroke as I have seen it in Hindostan; and it now only remains for me to say a few parting words about it, and then take my leave of the subject for ever. For one who has never been out of England, or who has not lived in it near a lime-kiln, or over a baker's oven, with all their outlets closed, and no companion but a panting dog or a drowsy domestic, it is hard to realise the exhaustion and *ennui* that result from a protracted residence under a brazen sky in the plains of India. With

(*a*) This strange language and theory were accepted with apparent approval on its part a few years ago, by no less an organ of public instruction or opinion than the *Daily Telegraph*.

the glass, it may be, at 90° in the shade, and the sand-charged blast either "roaring fiercely" (65) outside, or reduced to a minimum within, the predominant feeling must be one of weariness and depression. This weariness often begets restlessness, while the latter provokes thirst, and both tend to irritate and unnerve the mind, and deprave or destroy the digestion. The enforced solitude and inaction have a further tendency to constipate the bowels, while the drain on the skin induces a craving for drink, which can only be gratified literally at the point of the bayonet, and I am decidedly of opinion that when the surface temperature reaches 105°, or the atmospheric heat goes up to 120°, the least enhancement of either may turn the scale even for the strongest.

For the *rationale* of this phenomenon we must look to the mole cular condition, or, better perhaps, to the morphological appearances of the blood during life or after death, and we ought, I think, to cultivate a better acquaintance with the post-mortem thermometry of the viscera than now obtains.

I now much regret, as I have said before, that I did not pay more attention to these matters when I had the opportuuity, but *non omnia possumus omnes;* I did my best with the materials at my command, and no more than this ought in reason to be expected from any man. The subject is a very comprehensive one; the climate is unsuited for minute analysis or laboured experimentation, and military surgeons with belongings are unable to make room for microscopes or other costly apparatus. I have supplied the dry bones; it is for others to bind up these and clothe them with flesh. I have said my say and finished my self-imposed task, and if aught advanced within will help anyone towards a fuller conception of the situation than I have been able to attain, I shall be more than repaid for the labour and time this essay has cost me.

---

(61) See especially the evidence of Professors Turner and McKendrick; and Dr. Lauder Brunton thinks that (the *Practitioner*, vol. xi., p. 241), "both in fainting and shock the vessels are dilated, the blood-pressure low, and the circulation languid. . . . The arterioles, as is well known, are controlled by the vaso-motor centres in the medulla oblongata, and when this is stimulated, they contract, so that the blood pressure rises."

(62) Section xiii., from line nineteen to line thirty inclusive.

(63) I saw blood actually extravasated into the ventricles in one instance, thereby constituting, as I believe, the *apoplexie foudroyante* of the French pathologists.

(64) Alluding to the anxiety and exposure to which Sir Charles Napier and his army were subjected after the battle of Meanee, his brother, Sir William, says (*op. cit.*, part ii., p. 436), that "thus oppressed with care, with fatigue, fever, and want of sleep, the General was suddenly sun-stricken, and at the same time thirty-three Europeans fell at once near him beneath the malignant rays; most of them died within a few minutes, and all of them were dead within three hours; the General only survived," and the amusing and withal very characteristic description he himself supplied subsequently of this event may be seen in his "Life and Letters," by the same author. Malleson ascribes (*op. cit.*, vol. i., p. 458) the greater part of the fatality that occurred from this and other diseases within the Residency in '57, &c., to "the exposure, the fatigue, the want of rest, and the inferior nourishment" to which the garrison was subjected; and I believe, as the result of much inquiry on the point, that more men actually succumbed to this disease, *during the crisis of the mutiny*, than fell by the fire of the Sepoys.

(65) The readers of the interesting chronicles of Dustypore need scarcely be reminded of the source of this somewhat startling but withal very appropriate phrase; and looking out through my darkened window into the murky, eddying expanse outside, while the punkah flapped lazily to and fro within, and the (so-called) brain-fever bird piped his monotonous carol from a neighbouring bough, I have often asked myself, long before I had even heard the name of Mr. Mallock, if "life was worth living" on such terms.

THE Rev. Canon Miller, who died last week, was one of the founders of the Hospital Sunday Fund in Birmingham, which has since borne such excellent results throughout the kingdom.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY, F.R.C.S.I., M.B.

(*Continued from page 26.*)

Large Nasal Polypus.—A groom, æt. 18, from whose left nostril polypi had been removed five years previously at the hospital, returned with it blocked again, having enjoyed complete relief till the past ten months. There was now very considerable facial deformity. The carefully-introduced loop of a snare found the neck of the polypus high up, and in the extraction brought a minute scale of bone therewith. The growth had various diverticula; in structure it was of the ordinary muco-gelatinous type, and weighed 9 drams 40 grains.

Wound of Thorax perforating Lung.—A labouring man, of occasionally intemperate habits, æt. 45, was admitted shortly after being stabbed with a knife on the left side of the chest in a drunken brawl. The wound, an inch long, was external to, and on a line with nipple; before admission it had been closed by two points of interrupted suture. Subsequent to its closure considerable emphysema, extending down the side of the chest into the axilla over the front of the pectoral muscle, and up into the root of the neck, had occurred. The patient had spat a few blood-streaked sputa, which, however, he said was no unusual occurrence when suffering from exacerbations of a chronic bronchitis. Pledgets of lint soaked in compound tincture of benzoin were laid over the wound, which was surrounded by a ring compress firmly strapped and bandaged in position, so as to prevent further air effusion. Patient was seriously enough ill for some days with his bronchitic trouble, but seemed in no way the worse for his accident. The emphysema rapidly absorbed, and in ten days the man left the hospital in his usual health.

Extensive Compound Depressed Fracture of Skull—Elevation—Recovery.—Amongst the group of casualties admitted to the hospital from the conflagration of the Theatre Royal, was a healthy man, a gas fitter, æt. 31, on whom bricks from the parapet of a wall 45 feet high had fallen. A nearly horse-shoe-shaped wound extended from the centre of the left eyebrow to about an inch and a-half above a corresponding point on the right side, the convexity of the wound dipped well up into the region of the hairy scalp, the flap so outlined was turned down, exposing the bone stripped of periosteum, split longitudinally in an oblique manner and depressed around the entire circumference, being wholly beneath the surrounding skull; above a piece about the size of a shilling was completely detached at various parts, pieces of the circumferential inner table had been broken off, and depressed with the main piece. Moderate bleeding, evidently from the superior longitudinal sinus, welled up here and there, where the vent under the depressed bone was least obstructed. There were no symptoms. Viewing the depressed bone (some of the spicula of which could be seen imbedded in the dura mater) as a foreign body of the worst kind, a source of dangerous irritation, it was determined to elevate it. The operation was proceeded with between two and three hours after the occurrence of the accident, the depressed bone being got out by careful manipulation of elevator and bone forceps. (*a*) The jagged and spiculated edges of the gap in the skull were smoothed by nipping projections away with a "gnawing forceps." Pressure with a pledget of lint readily arrested the bleeding from the longitudinal sinus. Immediately after the operation, which was performed under chloroform, patient vomited profusely. Four hours after the clots were sponged away from the surface of the dura mater, the lint compress removed, there being no bleeding, the flap was turned into place and supported with compresses and strips of plaster, with provision for drainage from the extremities of the wound. Pulse 96, temp. 99°. Ice to head, and James's powder internally. At midnight the catheter was passed; the patient had slept and taken some milk. There was considerable serous discharge from the depending angles of the wound. For some days this outflow continued abundant, and gradually became purulent. Pulse and temperature both kept oscillating at 100. Locally, warm water dressings alcoholised were found to agree best with the wound. On the fourth day a purgative enema was given, and next

(*a*) One with a double rectangular beak, well known in American hospitals, was specially useful in guarding against further depression of the distal ends of the fragments.

morning the pulse was down to 84. The eighth day after the accident the facial aspect was observed not to be so good, the granulation looked pale and flabby ; the subsequent night delirium suddenly occurred, pulse being 100, temperature 102°. The condition was considered to be one of traumatic delirium rather than an indication of brain inflammation, and was met with a twenty-grain dose of quinine, with six ounces of whisky. In the morning improvement was manifest, but towards night recurrence of the special symptoms took place. Chloral and bromide failing to procure sleep, half a grain of morphia was given subcutaneously. This was followed by sound sleep for the remainder of the night. For some days there were occasional minor recurrences of restlessness and delirium, always controlled by the morphia, the pulse, however, not exceeding the 100. Exuberant granulations of the wound required to be now and then touched with nitrate of silver. On the 23rd day patient was allowed to sit up ; he had been quite rational and collected, but on the change to the upright position seemed for the first few days to have added confusion and mal-association of his ideas ; this state of affairs, however, wholly passed away after a little time. In six weeks the entire wound healed, except a sinus at the top, which led down to a bit of necrosed bone. On the 45th day the patient was allowed home, in every respect in perfect health, wonderfully little pulsation to be felt over the large extent of lower uncovered brain. The patient attended occasionally as an extern, the sinus remaining open till three months nineteen days, when a considerable-sized splinter was extracted by the forceps. The little wound repaired rapidly, and it would be difficult, save for the known unprotected state for the brain, to say how the man was the worse for his accident. The total of bone elevated was not less than seven square inches. The pieces form, roughly speaking, an irregular triangular plate, with expanded apex, the circumference being nearly eleven inches.

The Mineral Waters of Europe.

ANALYTICAL REPORTS ON THE PRINCIPAL MINERAL WATERS, FOR THE GUIDANCE OF THE PROFESSION AND THE PUBLIC.

By CHARLES C. R. TICHBORNE, LL.D., Ph.D., F.I.C., President of the Pharmaceutical Society of Ireland, &c.

WITH NOTES ON THEIR THERAPEUTICAL USES.
By PROSSER JAMES, M.D., M.R.C.P. Lond., Lecturer on Materia Medica and Therapeutics at the London Hospital.

(*Continued from page 518, last vol.*)

THE classification of mineral waters is a subject that presents great difficulty, and has been treated in different ways. The alphabetical arrangement would perhaps get over all difficulties, but would hardly facilitate the inquiries of the medical man. Mineral waters often differ in their temperature when examined at their source. Thus we have all degrees, from the Malvern waters below the atmospheric temperature, to the boiling springs of Iceland—from the almost ice-cold waters of Silesia, to the hot Sprudel of Bohemia : attempts have been made to classify them from these degrees of temperature. Such a classification might amuse the crotchets of our ancestors ; whilst of little use even to those who use the waters locally, it is utterly worthless for the purposes of these articles. The classification based upon the therapeutic action is very little better, owing to the complicated character of their remedial repute, and the still greater mystery which hangs about their therapeutic action.

Their general, or most marked chemical character appears to us to present the most feasible method of classifying mineral waters. One well known work proposes to classify them on this principle : but suggests the rather crude division of sulphurous, chalybeate, and saline. We propose as the main or primary classes five, namely : 1, saline or aperient ; 2, alkaline or antacid ; 3, ferruginous or chalybeate ; 4, sulphurous ; 5, potable or indifferent. The saline or purgative waters mainly owe their virtues to the large quantities of magnesium, or sodium sulphate, as in the Hunyadi János, where these two salts occur in nearly equal proportions and in large quantities. When the magnesian sulphate and chloride occur in large proportions the waters generally are known on the Continent as bitter waters, as they owe their bitterness to the above-named salts.

In the Kreuznach water of Prussia we have a saline water of another class in which, according to the published analysis, we have about 900 grains of salines to the gallon, and which is absolutely free from the presence of alkaline or magnesian sulphates. We are not justified in dividing such waters from the other saline waters, because if we exclude any special action of the other ingredients they still remain purgative water, and very frequently are generally associated chlorides and sulphates ; perhaps we might further classify the saline water as "haloid saline," sulphuric saline, or, when combined, as "sulphuric-haloid saline."

The alkaline waters generally owe their alkalinity to the carbonates or bi-carbonates of the alkaline earths conjointly with the potassic or sodic carbonates. The antacid properties are, of course, more marked with those waters which contain a sensible quantity of the alkaline carbonates, chiefly sodic and potassic bicarbonates ; whilst the lithium, and other alkaline earths, are specially indicated in urinary diseases.

The term "alkaline acidulated springs" is sometimes used in connection with these waters. We confess we hardly understand the term or the sense in which it is used, because, in many lists, it seems to be applied indefinitely, and just according to the *caprice* of the writer. We find in waters similarly constructed, some are so named, whilst others are not. Almost all these waters, from a geological necessity, must contain free carbonic acid gas, and, in a sense, are acidulated ; but the loss of the excess of that gas must result, probably, in an alkaline condition, but certainly in a neutral liquid.

Ferruginous or chalybeate waters contain the iron, in three conditions, either as a ferrous or protocarbonate of iron, or as a basic or neutral sulphate. It is generally present in either of the two first conditions, and although the protocarbonate is considered the most useful and valuable form, (it is certainly the one most pleasant to take), it is not so permanent a water for bottling.

(*To be continued.*)

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Hull 10, Birmingham 13, Brighton 15, Portsmouth 16, Leeds 17, Wolverhampton 17, Nottingham 18, Newcastle-upon-Tyne 19, London 19, Edinburgh 19, Leicester 19, Sheffield 19, Plymouth 20, Bradford 20, Manchester 21, Glasgow 23, Salford 24, Sunderland 24, Liverpool 25, Oldham 29, Norwich 30, Dublin 31.

ANNUAL MEETING OF THE GENERAL MEDICAL COUNCIL.

THIRTIETH SESSION.

Dr. ACLAND, M.D., F.R.S., President, in the Chair.

FIFTH DAY.—MONDAY, JULY 12TH.

THE minutes of the meeting of Saturday were read and confirmed.

The Council resolved itself into committee to continue the debate on

PRELIMINARY EDUCATION.

Prof. TURNER moved, Dr. ROLLESTON seconded, that one ancient language, either Latin or Greek, be made compulsory.

Dr. HAUGHTON said he should move an amendment to the effect that the Council considered English the only language *essential* to a medical student. He doubted the right of the Council to legislate for the higher education of members of the medical profession. The preliminary standard was too low for the more accomplished, and too high for the inferior branches of the profession. The training of men for the loftier branches of practice ought to be left to the Universities. But the rewards of a general practitioner are too low to expect him to cultivate *belles lettres*. Dr. Haughton would, he said, insist on an efficient technical education for *every* medical man. He therefore moved that the Council should declare the English language to be the only essential language to be required from a medical student. Dr. Haughton quoted a return received that morning of the number of candidates at the recent intermediate examination in Ireland. This showed the total number to be 3,218; of these 1,209 offered Greek, 2,120 Latin, 1,602 French, and 121 German. This return, he said, was most interesting. It applied to a class of young men from whom Irish medical students were drawn, and proved the favour shown to the ancient languages. It would be an injustice to these large numbers to place an obstacle to associating Greek and Latin in the preliminary Arts examination. He thought the function of the Council was to legislate for the great mass of men who were to become general practitioners, and to ensure their pursuing their calling with safety to the public; and he concluded a most eloquent, able speech in defence of the English language, by urging the acceptance of his resolution.

Dr. HALDANE seconded the motion. He thought Latin a most desirable element of a student's knowledge, but the reasons for making it a compulsory subject were insufficient. The great majority of men were not benefited by the knowledge of Latin acquired during the preliminary training. He quoted prescriptions written by candidates which conclusively proved this statement. Times have changed, said Dr. Haldane. Formerly the whole medical training was based on the Latin tongue, and the language was essential, but in the present state of things it differed greatly. Latin was a cause of rejection for the great majority of candidates.

Dr. ROLLESTON had been inclined to regard Dr. Haughton's motion as a joke, but Dr. Haldane's support was to make it important and grave. He quoted Sir Robert Christison's evidence before a Royal Commission, in which that gentleman expressed his belief that certain bad changes had occurred in the profession. Speaking of the training of students he averred this was not so good as formerly; they may know more, but they know it less well. He further said he knew nothing more admirable as a training for young men than Greek and Latin. Dr. Rolleston besought the Council not to overthrow the common bond which gave the medical man status with the other learned professions. While these intensified their hold on Latin ought the Council to neglect it on behalf of the medical profession? Dr. Rolleston quoted numerous authorities in support of his defence of the Latin language. He urged the usefulness of Latin as not being disproved by Dr. Haldane's exposures. A language can be understood without the power of composition in it, and such a knowledge may confer all the essential advantages following from its study.

Sir WM. GULL thought the question should rather have been referred to the College of Preceptors. That body would be better able to gauge the capacities of the young men they had to deal with. The Council ought only to demand an examination in the subjects taught in schools generally, but not to dictate what must be taught.

Dr. BANKS contended that general education was on a higher level than in Scotland, and he knew that men who went to the Queen's University, Ireland, for a degree were oftentimes compelled to resign their intention. He thought the standard should be raised rather than lowered.

Dr. HAUGHTON explained that he was perfectly serious in bringing on his resolution.

The amendment was then put to the vote and lost.

The original motion of Dr. Turner being put—

Mr. MACNAMARA moved "That the present recommendations, so far as Greek, Latin, French, and German are concerned, do stand." He pointed out that it would be an injustice to the Irish students, who would be required by the University of Dublin to produce both Greek and Latin.

Mr. TURNER objected that Mr. Macnamara's resolution was not an amendment to his motion.

Mr. MACNAMARA assenting, deferred his amendment till the consideration of Mr. Turner's motion (*c*).

Dr. A. WOOD moved "That one of the compulsory subjects be Latin, including grammar and composition;" but after some discussion the (Mr. Turner's) original motion was passed.

Mr. TURNER then proceeded to move a resolution to give an option between Latin and Greek, which was seconded by Dr. Pyle.

Dr. A. WOOD objected to the alternative. He thought it would be a retrograde movement to pass from their determination to require every student to pass an examination in Latin. He did not deny the utility of English, but thought Latin must be continued. He did not want to see Greek omitted, but would insist on the retention of Latin.

Dr. STORRAR seconded the motion of Dr. Turner. He said it is generally declared that men unable to pass in England resort to Edinburgh, and successfully undergo the preliminary examination there.

Dr. ROLLESTON insisted that there was no fear of Latin being displaced in schools. Greek, he showed from the report of the annual conference of schoolmasters, is studied by only a small minority of students.

Mr. SIMON agreed with Prof. Rolleston that the system ought to be allowed.

Prof. HUMPHRY felt that recognition was being forced, for the fact that sciences were as good bases of preliminary education as the ancient languages. In fact, high class examinations were now conducted on this assumption. And a feeling was growing that Greek and Latin were equally valuable as a means of intellectual training.

Dr. QUAIN thought Latin essential to a medical student.

Mr. TURNER pointed out the difference between his own and Dr. Wood's motion. The latter sought to make Latin compulsory, by keeping things as they are. His own resolution sought to afford an option between Greek and Latin.

Dr. WOOD'S amendment being put, an equal number voted for and against; but on a count the motion was carried by a majority of one, and being put as a substantive motion was carried.

Mr. TURNER then proceeded to move "That one modern European language be made compulsory at the preliminary examination." The necessity of the subject was, he said, growing daily greater, from the number of books printed in French and German, and of infinite service to students. He advised giving an option of more than these two languages, however, for Italy was becoming daily more actively engaged in medical investigations. Dutch also he named as being important in its scientific aspects, likewise the Scandinavian languages.

Dr. BANKS seconded the motion.

Dr. HAUGHTON saw in the course the Council was pursuing a danger of clashing with the higher examining bodies. The new regulation would require a graduate in Arts, for instance, from Oxford or Dublin entering the medical profession to pass a new preliminary examination, since modern languages are not compulsory at these institutions. The risks of interfering with the higher bodies by such a regulation are very great.

Mr. TURNER said there was no intention to require a holder of an Arts degree to pass the preliminary examination.

Prof. HUMPHRY moved an amendment that Greek, French, and German be optional subjects as at present.

Dr. A. WOOD seconded the amendment. He urged the injustice of forcing another subject on the candidate.

Dr. PETTIGREW supported the amendment, on the ground that too high a standard would reduce the supply of students.

In case the amendment succeeded in passing, he would support the introduction of "mechanics" as a subject of examination.

Sir WM. GULL said he had noticed that the great public schools would keep clear of the medical profession if modern languages were required as a *sine quâ non* of registration.

Prof. ROLLESTON insisted that the Council must seek to make the examination the best for the time, and not the best suited for this or that school. There could be no need for introducing a modern language as there is for retaining an ancient language in the examination.

The amendment was withdrawn, and the motion then put to the vote and lost by a large majority.

Mr. TURNER moved "That an examination in the elements of mathematics form a necessary part of the preliminary examination," which was carried.

The three parts of the examination were then proposed, viz :—(*a*) Arithmetic, including vulgar and decimal fractions ; (*b*) Algebra, including simple equations; (*c*) Geometry, including the first three books of Euclid.

Mr. SIMON advised extending the algebra to quadratics.

Sir JAS. PAGET saw no advantage in retaining the subject at all.

Prof. ROLLESTON advised the addition of inductive and deductive logic as an alternative for Euclid and algebra, and put this as an amendment.

The amendment to increase the amount of algebra was put to the vote and lost.

Dr. ANDREW WOOD thought undue burdens were being added, and would advocate reducing the amount of work.

Dr. HALDANE having spoken,

Mr. TURNER insisted that algebra is essential to a student of chemistry, and should not be omitted.

Dr. HAUGHTON objected to separating algebra and Euclid. They must be studied together to be of service. He was willing to see the amount of the subject named by Prof. Turner increased.

Dr. HUMPHRY said the preliminary examination of Cambridge University is a hard one, and he felt to extend the subject as the Council was begged to do was detrimental. He would propose an amendment to leave the subject of mathematics as it was.

Mr. SIMON supported Dr. Rolleston's amendment.

A desultory discussion followed on immaterial points. in which Drs. Rolleston, Humphry, Sir Wm. Gull, &c., joined.

SIXTH DAY.—TUESDAY, JULY 13TH.

PRELIMINARY EDUCATION.

The Council went into Committee for the consideration of the adjourned motion on preliminary examination.

Mr. Turner's motion—"That the examination in mathematics include algebra and simple equations," was put and carried.

Mr. TURNER moved that the examination in geometry include the first three books of Euclid, or the subjects thereof.

Dr. ROLLESTON moved as an amendment the addition of the fourth book of Euclid.

This was put and negatived.

Dr. HUMPHRY proposed another amendment, to the effect that two books of Euclid only, as at present, be required, and this was carried by a large majority.

Mr. TURNER said that, judging from the spirit which had been manifested by the Council, he feared that the motion he was about to make with regard to the elementary mechanics of solids and fluids might be rejected. Last year, however, a resolution on the subject had been passed by the Council, and the only reason why it had not been confirmed was that the Executive Committee found that there were certain technical difficulties in the way. All he asked of the Council at present was its sanction to the general proposition "that the elementary mechanics of solids and fluids should form part of the preliminary examination." There might, however, be some difficulty in forcing the subject into the preliminary examination, because there were so many schools in which it was not taught; and he would therefore add to his resolution—"It being understood that the examination in this branch may be passed either as preliminary, or before, or at the first professional examination."

Dr. HAUGHTON, in seconding the motion, said the subject included in it was absolutely necessary for the furniture of a student's mind. So great was the ignorance on the subject on the part of army officers in India that some of them did not know the difference between a barometer and a thermometer.

Dr. PETTIGREW approved of the introduction of the subject, but thought that it should be rendered compulsory before the commencement of the medical curriculum, and he moved an amendment to that effect.

Dr. A. SMITH expressed a similar view, and seconded the amendment.

Mr. TURNER suggested that his motion should be divided into two parts, and that a vote should be taken on the simple question that there should be an examination in the elementary mechanics of solids and fluids, making the period at which it was taken the subject of a distinct motion. This course was agreed to, and the question was unanimously decided in the affirmative.

Sir W. GULL ridiculed the idea of the Council going over the same ground as last year, and said they appeared to be constantly deciding the same thing over and over again, and always congratulating themselves on their success.

Dr. Pettigrew's amendment was then put and negatived, and Mr. Turner's motion—"That the examination in the Elementary Mechanics of Solids and Fluids comprise statics, hydrostatics, and dynamics," was agreed to by a large majority.

This concluded the discussion on compulsory subjects.

OPTIONAL SUBJECTS.

Dr. FERGUS then brought forward a motion relating to the optional subjects. He said he had been accustomed to regard the Council as a body which aimed at elevating the education of the profession, but he was now afraid that they had been levelling down instead of up. They ought to have increased the stringency and breadth of the examinations. More than one-third of the candidates who came up to the first professional examination were rejected. Such a state of things ought not to exist. The preliminary examination should be such as would weed out the incompetent, and therefore should be greatly extended. Instead of that the Council had for the last few days been bringing the examination down to the level of boys fresh from school. The Council should not try how rapidly they could manufacture doctors, but in every way to elevate them. He moved: "That one of the following optional subjects must be passed as preliminary—namely, French, German, Italian, Dutch, Greek, Logic, Moral Philosophy, Botany, Chemistry, Zoology, Geology."

Dr. ROLLESTON seconded the motion.

Mr. SIMON said he was not quite clear that even one optional subject was necessary, but he thought a distinction might very properly be drawn according to whether or not the examination in the elements of mechanics had been passed as a part of the preliminary. He was disposed to think that if a candidate practically said, "My educational circumstances have not allowed me to learn elementary mechanics in time for the preliminary examination," an optional subject should be required. In that way he would hold out an inducement to the students to pass the examination in elementary mechanics as a preliminary, and if they did so they should be excused from all the optional subjects.

Dr. HAUGHTON thought chemistry and moral philosophy should be excluded from the list. The Council would have a very mean opinion of what chemistry was if they considered the wretched schoolboy knowledge as sufficient.

After discussion elementary chemistry was retained among the list of optional subjects, but moral philosophy, zoology, and geology were thrown out. The other subjects embodied in Dr. Fergus's motion were agreed to, and the Council adjourned.

SEVENTH DAY.—WEDNESDAY, JULY 14TH.

THE ARMY AND NAVY MEDICAL SERVICES.

On the reassembling of the Council,

Mr. TURNER asked the President if he could furnish the Council with information why the Naval Medical Department had ceased to furnish a statement of the results of the examinations for admission to the Medical Department of the Navy; also if the returns for the Army Medical Department include the candidates for commission in the Medical Department of the Indian Army.

The PRESIDENT replied that there had been some delay in obtaining the desired information, and he was unable to give a complete answer. He had reason, however, to believe, from communications he had had with both Departments, that there would be no difficulty in obtaining the information.

Dr. HAUGHTON said that the subject was under the notice of

Parliament, and it was important that the information asked for should be communicated.

The PRESIDENT said that as soon as it was received it should be communicated to the Council.

PRELIMINARY EXAMINATION.

The debate on Mr. Turner's motion for the adoption of the resolutions passed by the Council with regard to preliminary examination was resumed.

The following resolutions were adopted without discussion :—(1) "That an examination in English form part of the preliminary examination." (2) "That the examination in the English language be such as is now provided for in the 'Recommendations' of the Council, except that the last two lines of the footnote to p. 8 of the last edition of the 'Recommendations' be in future omitted."

On the motion (3) "That No. 2 of clause 4 of the 'Recommendations' be as follows: either English history or modern geography,"

Dr. QUAIN suggested the substitution of the word "and" for "or," and contended that the two subjects could not well be separated.

Mr. Turner adopted the suggestion, and the motion was altered accordingly and agreed to.

The following resolutions were adopted without discussion :—(4) "That an examination in one ancient language form a part of the preliminary examination." (5) "That Latin, including translation from the original and grammar, be the ancient language which is to be rendered compulsory." (6) "That an examination in the elements of mathematics form a necessary part of the preliminary examination." (7) "That the examination in mathematics comprise : (*a*) arithmetic, including vulgar and decimal fractions." (8) "That the examination in mathematics comprise : (*b*) algebra, including simple equations." (9) "That the examination in geometry comprise, as at present : (*c*) geometry, the first two books of Euclid or the subjects thereof." (10) "That there be an examination in the elementary mechanics of solids and fluids." (11) "That it be understood that the examination in the elementary mechanics of solids and fluids may be passed either as preliminary, or before, or at the first professional examination, so that the passing of this examination is not to be regarded as necessary for registration." (12) "That the examination in the elementary mechanics of solids and fluids comprise the elements of statics, dynamics, and hydrostatics."

Mr. TURNER proposed the adoption of the next resolution :—(13) "That the following be the optional subjects : Greek, French, German, Italian, or any one modern language, logic, botany, elementary chemistry."

The proposition, after one or two amendments had been negatived, was agreed to.

It was then resolved, "That one of the foregoing optional subjects be made compulsory."

On the motion of Mr. TURNER, seconded by Sir JAMES PAGET, the following resolution was agreed to :—"That the General Council's amended Recommendations on education and examination be communicated to the several examining boards whose examinations are recognised by the Council ; that their attention be drawn to the changes which have been made ; that they be informed that the Council proposes that the additional requirements be not made obligatory on students until Jan. 1st, 1882 ; and that on and after that date no person be allowed to be registered as a medical student unless he shall have previously passed a preliminary examination in the subjects of general education as specified in the following list" (the list agreed to during the present session).

Mr. SIMON proposed, "That, in the opinion of the Council, it is desirable that intending candidates for the medical profession should, before they enter on the purely medical curriculum, have been instructed and examined in the rudiments of natural science—physical, chemical, and biological, and that, in proportion as this can be done, the present medical curriculum and present professional examinations should be lightened of all such matters." He said there was no reform on which competent persons were more entirely agreed than the necessity of their getting, if possible, a preliminary scientific examination ; it would be a most important assistance to the progress of medical education in this country.

Dr. FERGUS seconded the motion.

Mr. TURNER said he was entirely at one with Mr. Simon as to the importance of having an examination in the natural sciences as a part of the general training required from students of medicine, and that the examination on these subjects should, of course, take place before the examination in subjects more directly bearing on medical training.

Sir JAMES PAGET was satisfied that no conclusion could be arrived at on this subject during this session of the Council, and, therefore, if Mr. Simon's motion was adopted it must be on the understanding that it should not come before the Council, but should be referred to a committee.

Sir WILLIAM GULL, in supporting the motion, said the result would be that more time must be occupied in the study of the profession than was the case at present. It was quite impossible to educate a man so that he should be fit to enter on the practice of his profession at the age of twenty-one. It could not be done, and, therefore, they ought to ask that a man should be twenty-three at least, and perhaps twenty-four, before he was entitled to practise. In making this inquiry they certainly must take in the whole question of professional time.

Dr. HAUGHTON said the practice of the University of Dublin was precisely in accordance with the proposal of Mr. Simon, the Arts curriculum and the medical teaching occupying together six years. He did not object to the resolution, but it must involve an additional time of study after registration before commencing practice.

The motion was then put to the Council and agreed to.

Mr. SIMON, after expressing his gratification at seeing the principle of his resolution so entirely approved by the Council, moved : "That this resolution be referred to a committee of seven, with instructions to propose to the Council before the close of the present session the draft of a communication to be addressed to the licensing authorities with a view to giving it practical effect." He did not propose anything like a committee of investigation, but simply a committee to draw up a letter to be sent to the licensing bodies.

Dr. FERGUS seconded the motion.

Mr. TURNER thought there would be some difficulty in getting a satisfactory communication drafted and approved by the Council this session, as it would no doubt involve some discussion.

Dr. HALDANE, although entirely agreeing with the principle involved in Mr. Simon's resolution, would not vote for it, because it involved so complete a change in medical education. This was a point of very great importance, and the Council should not take action in the matter without consulting the various licensing bodies. He therefore proposed as an amendment, "That the Council having agreed to the preceding resolution, a copy of this resolution be sent to each of the licensing bodies, with a request that they will at an early date express their opinion on the subject."

Dr. ANDREW WOOD seconded the amendment.

After some further discussion Dr. Haldane's amendment was put in the following form : "That a committee be appointed to communicate on the subject with the licensing bodies, and to report to the Council at its next meeting." This was agreed to.

On its being put as a substantive motion,

Mr. MACNAMARA moved as an amendment : "That this resolution be referred to a committee of seven, with instructions to propose to the Council before the close of the present session the draft of a communication to be addressed to the licensing authorities, with a view of getting their opinion thereon."

Mr. SIMON seconded the amendment, which on being put to the Council was negatived by a majority of 10 to 9.

The motion as proposed by Dr. Haldane was then put and agreed to.

The Committee was appointed, comprising Dr. Storrar, Dr. Rolleston, Dr. Hudson, Mr. Turner, and Dr. Haldane, with power to add to their number.

AN APPLICANT FOR REGISTRATION.

An application for registration by Mr. Nathaniel Chappell, referred to the General Council by the executive committee, was refused.

The Council then adjourned.

EIGHTH DAY.—THURSDAY, JULY 15TH.

The minutes of the preceding day's business having been read and confirmed,

Mr. TURNER moved "That the bodies conferring licences in dental surgery be requested to furnish each year on or before Jan. 1, according to the following form, a statement of the nature of the examinations—whether written, *viva voce*, or practical (one or all of the three)—and of the number of can-

didates for their licences, showing the respective numbers passed and rejected."

FORM FOR THE TABLE OF RETURNS OF PROFESSIONAL DENTAL EXAMINATIONS AND THEIR RESULTS.

Licensing Bodies.	Diplomas.	Nature of Examination.	With Curriculum.		Without Curriculum.	
			No. Rej'ct'd	No. Passed	No. Rej'ct'd	No. Passed
Total ..						

Mr. TURNER said he had been led to this course by the consideration that the information which would be thus obtained would be very valuable in enabling the Council to determine on the efficiency of the examinations, and the manner in which the Council's recommendations are being complied with.

Dr. STORRAR seconded the motion, which was carried.

On the motion of Dr. QUAIN, seconded by Prof. HUMPHRY, memorials from the Association of Surgeons practising Dental Surgery, and from the British Dental Association, were decided to be entered on the minutes.

Dr. PITMAN then drew attention to a letter from the Hon. Sec. of the British Dental Association, and other papers dealing with the improper entry of names on the Dental Register, and moved that the subject be referred to the Dental Committee.

Dr. STORRAR wished to inform the Council of another source of information. He said a legal opinion had formerly been obtained in reference to the question, and which had never been included in the minutes.

Dr. PITMAN said the matter could be explained; a succeeding motion would deal with all the documents received.

Dr. PITMAN moved :—"Certain persons having requested that the words 'with Pharmacy' be omitted after their names from the *Dentists' Register*, it is recommended that the Council refer all such cases to the Dental Committee to ascertain the facts in each of such cases;" which being seconded, was carried.

Dr. QUAIN moved, "That the opinions on the subject of dental registration, specified in the minutes of the Executive Committee for Nov. 28, 1879 (*Minutes*, vol. xvi., p. 434, clause 3), be referred, with all preceding documents, to the Dental Committee."

The REGISTRAR read one of these documents, which consisted of a letter from Mr. Tomes, already contained in the Council's minutes (vol. xvi., p. 468).

Dr. QUAIN said the opinions expressed heretofore were of a contradictory kind, and he thought the Council would be wise to submit the matter to the Dental Committee before considering it.

Dr. STORRAR said he could see no objection to inserting counsel's opinions in the minutes, as proposed by Dr. Quain. They should be familiar to every member of the Council, and not hid as secret documents for the perusal of a committee alone.

Mr. SIMON thought it indispensable that the Council should be in possession of all information likely to influence its decisions. The publicity of such a course could not be objected to. No matter should go to a special committee before the consideration of it by the General Council.

Mr. TURNER did not understand the matter.

The PRESIDENT explained that Mr. Ouvry was present, and would afford any information desired to make all clear.

Dr. ROLLESTON suggested an alteration in Dr. Quain's motion.

Mr. TURNER asked that Mr. Ouvry would explain the powers of the Dental Committee, as defined in the clause under which it held office. He felt it should be known whether the General Council had any power to revise the Dental Committee's proceedings.

Mr. OUVRY explained that the Dental Committee cannot initiate any movement, but can only proceed after questions have been referred to it by the General Council. It must report on those, and can do nothing more of its own power than state and ascertain facts for the Council's guidance. As to publishing counsel's opinions, Mr. Ouvry thought the usual course of the General Medical Council in not printing such opinions the wiser course to pursue.

Dr. PITMAN thought the discussion out of place, since the Council would not be called on to act till next year in regard to the matter.

Mr. MACNAMARA said this was a wrong impression, for he had a motion on the paper in regard to which the Council would be required to act immediately.

The PRESIDENT said this was a different matter.

Dr. STORRAR urged the necessity for laying the opinions of counsel before the General Council.

Dr. PYLE asked if the names now on the Register must remain till next year, and was answered in the affirmative.

Dr. AQUILLA SMITH proposed that the opinions of counsel be read.

Dr. QUAIN said 360 cases had been that day referred to the Dental Committee, and they would be guided in their action by the opinion of counsel.

Dr. A. WOOD advised reading the opinions.

The PRESIDENT agreed with Mr. Simon that the business could be proceeded with without Dr. Quain's motion at all. The opinions of counsel were there in the office, and accessible to any member of the Council. They were not published in accordance with the advice of the Council's legal adviser.

A proposal by Mr. TURNER to read the opinions in private was opposed by the Rev. Dr. HAUGHTON, but on a division was carried, and strangers were thereupon requested to withdraw.

PRELIMINARY EDUCATION.

Mr. SIMON moved :—

"That, in Section 3 of Chapter 1 of the Council's *Recommendations on Education and Examination*, the List of Bodies from which Testimonials of Proficiency in Preliminary General Education may, in the opinion of the Council, be properly accepted by the Licensing Authorities under the Medical Act, be amended by omission of its Part II.; this amendment to take effect on and from the 1st of January next; and that notice be forthwith given to each licensing authority that, after the end of the present year, the examinations mentioned in Part II. of the aforesaid list will not be regarded by this Council as satisfactory for the purposes of the Medical Act."

The object of preliminary education was, he said, to ensure that men who entered the medical profession should be educated gentlemen. This could only be ensured by insisting the test should be applied by non-professional examiners. This was the intention of the resolution. Mr. Simon repeated at some length much of the evidence already frequently quoted in previous discussions before the Council, respecting the action of the Council, from time to time, on the subjects of preliminary examination. He referred to the reports presented from the branch councils, the chief point of which was that preliminary examinations conducted by medical examiners cannot commend themselves to the favour or confidence of the profession. The necessity for the examinations he sought to strike out, existed, he contended, no longer. There had long been the impression that they were improper tests, and any recommendation which it was thought was out of place, ought to be rescinded.

Dr. STORRAR seconded the motion.

Mr. MACNAMARA denied that the corporations are more open to the charge of admitting men into the medical profession after a lenient examination than are universities, but he repudiated any desire on the part of either to pass a candidate unfairly. So far as the R.C.S.I. was concerned, the examiners at the preliminary test were gentlemen resident far away from the scene of examination, and could be influenced by no wish to swell their classes by passing men too easily. He would say that his college would challenge any attempt of the Council to wrest its privilege of examining men, and would force the matter to the Privy Council. No vote of the Medical Council can settle the matter, and he would implore it to pass no recommendations, to which no attention will ever be paid, except under compulsion. The Council had neglected its duty by failing to order visitation of the examinations complained of. It ought not to condemn any examination until it has investigated the character of it. In time the Irish College of Surgeons might be able to give up its preliminary examinations if the intermediate education scheme worked well in Ireland.

Prof. HUMPHRY agreed that preliminary examinations

ought not to be conducted by medical examiners. The principle was admitted by a majority of the Council, and he hoped no long or energetic defences of special bodies, none of which were individually incriminated, would be entered on. The wishes of the Council were assented to by the Colleges of Physicians of England and Ireland. The College of Surgeons of England is willing to give up its preliminary examination, but does not see its way to doing so at once. He feared the passing of Mr. Simon's resolution would undo the impression made by the influence of the Council. The end in view would ensue only after a long time. The Privy Council would be unlikely to support the General Council in its action against recalcitrant bodies. Prof. Humphry pointed out that the Act gives the General Medical Council no power over general education, but only over the medical training of students; and he concluded by expressing sorrow that the motion had been brought on.

Mr. TURNER agreed in general terms with Prof. Humphry.

Dr. BANKS thought the preliminary examination should be conducted by Arts examiners.

Dr. A. WOOD pointed out that the motion differed from all former recommendations in being a compulsory measure. The bodies affected by the motion would resist the action of the Council.

Dr. ROLLESTON showed that the principle of the action was not entirely new, a resolution having been passed by the Council some years ago; and he thought the medical corporations ought not to examine in the subjects of preliminary education. The corporations are submitted to temptation by this means, and the Council should do its best to make this impossible. He thought an examiner should not remain in office more than two years.

Dr. HALDANE opposed the motion.

Dr. PITMAN could not vote for the motion, because though it is desirable, as the motion quoted by Dr. Rolleston averred, that preliminary examinations should be conducted by university boards, yet it was impossible. He showed that the Council, to be consistent, would be required also to refuse registration to the bodies who licensed men after passing one of the prohibited examinations. This it had no power to do.

Sir JAMES PAGET felt the motion of Mr. Simon was impracticable. The wishes of the Council had been attended to, and he deprecated the impression that the Council alone discussed such matters as this. The great corporations give, and have given, much time and attention to the subject, and it should not be disposed of in the way the motion strove to treat it.

Dr. STORRAR felt the motion would be better withdrawn, though, if pressed to a division, he should vote for it.

Mr. SIMON, yielding to the wish expressed by Dr. Storrar, sought permission to withdraw his motion, which being accorded, the Council adjourned.

NINTH DAY.—FRIDAY, JULY 16TH.

The minutes of the last meeting having been read and confirmed,

Mr. TURNER asked "the President if he can furnish the Council with information why the Navy Medical Department has ceased to furnish a statement of the results of the examinations for admission to the Medical Department of the Navy."

The PRESIDENT said he had received a letter from the first Lord of the Admiralty, saying there was no objection to the Council receiving the same information on the point as was afforded by the Army Medical Department.

Dr. HAUGHTON asked "the President to take into his consideration the propriety of holding the usual Annual Meeting of the General Medical Council during the Easter recess."

The PRESIDENT explained that since the foundation of the Council pains had been taken to fix the most convenient date of meeting. A general feeling in favour of a fixed date prevailed, but he thought this impossible. He would assure Prof. Haughton every pains would be taken in future to consult general convenience.

Mr. MACNAMARA asked "the President whether he can communicate to this Council the names of such of the authorities mentioned in schedule (A) to the *Medical Act* as accept, *ad eundem*, either in whole or in part, the 'previous medical examinations' conducted by other bodies, and if so, whether he will be good enough to give the Council this information, and to state in each case to what extent the acceptance goes."

The PRESIDENT had no information to enable him to answer the question.

A communication from the R.C.S.I. in reference to alleged mal-practice by Mr. John Hamilton was read, and Dr. A. WOOD moved the communications be entered on the minutes. This was carried.

Dr. ANDREW WOOD said this case had been referred to the Dental Committee, whose report was then read by the Registrar. The report explained that Mr. Hamilton's name had been removed from the licentiates R.C.S.I.

Dr. ANDREW WOOD moved the report be entered on the minutes; and this was carried.

Mr. MACNAMARA proposed that the name be struck out of the Dentists' Register.

Dr. A. WOOD moved that the case be referred for inquiry to the Dental Committee.

Dr. QUAIN seconded the motion.

Dr. STORRAR desired that some means could be devised for keeping the names to be struck off the Register out of the 1881 edition, and suggested a special meeting of the Council during the year to consider the question. The motion was withdrawn, and the amendment to refer to the Dental Committee carried.

Mr. MACNAMARA moved, "That all such bodies, the preliminary examinations of which cannot be visited by this Council, be removed from the list of bodies receiving its sanction."

Quis custodiet ipsos custodes? should, said Mr. MACNAMARA, be the inquiry guiding the action of the Council, whose duty it was to see that the examinations it admitted were efficiently conducted. There could be no certainty that a foreign body would accurately examine in the English language, essential as this is to a student of medicine in this country.

Dr. HAUGHTON seconded the motion, but said he would not go so far as the mover. He thought, however, the list of examinations unsatisfactory. He wished the whole list might be submitted to a committee of revision. The nine examining bodies of Canada, and seven of Australia and New Zealand, and other colonial centres, of which the Council could have as accurate knowledge, ought he considered to be inquired into.

Dr. STORRAR besought Mr. Macnamara to withdraw his motion for the present session, and be satisfied with drawing attention to the subject. He thought colonial candidates should be considered on individual merits.

The motion was withdrawn by permission.

Mr. TURNER moved, "That the 'Gymnasial Abiturienten Examen' in Germany, and the corresponding examinations in other continental countries, required for admission to their respective Universities, be accepted as qualifying for registration as a medical student." This examination, Mr. Turner explained, is that passed by students proceeding from the schools to the Universities, and corresponds in character with the higher class examinations admitted by the Council, but of an infinitely higher standard. It demands a sufficient knowledge of mathematics, languages, and science. The executive committee had from time to time admitted foreign certificates as equivalent proof of preliminary education, and it was right the advanced certificates named in the motion should be received. Mr. Turner showed the motion, if adopted, would have an important influence in liberalising the admission of foreign graduates to the English Register.

Dr. ROLLESTON seconded the motion, which was carried.

Motions dealing with standing orders relating to returns of passes and rejections of preliminary examinations and other matters, by Dr. FERGUS, were withdrawn by permission.

Dr. HAUGHTON moved that, "The General Medical Council are of opinion that the first medical examination should include a separate examination in Physics, meaning thereby the elements of heat, electricity and magnetism." The reason for this was, Dr. Haughton said, that from the common plan of including physics and chemistry in a single paper, the physical part of the examination suffers in extent.

Dr. BANKS seconded the motion.

Mr. TURNER said this motion came within the province of the committee appointed lately, and of which Dr. Haldane was chairman. He thought the mover should be content with calling attention to the matter.

Dr. HAUGHTON said he would be satisfied to refer the motion to Dr. Haldane's committee, and leave to do this was given in an amendment.

Mr. MACNAMARA moved, "That a Pharmacopœia commit-

tee be appointed, with the view of considering and of reporting to this Council how best any future edition of the 'British Pharmacopœia' may be brought up to the scientific standard of the present day." The existing Pharmacopœia was at the time of its production, Mr. Macnamara said, an admirable work, but the advance of scientific discovery and differences in nomenclature made it at this time an imperfect, inaccurate guide. The patchwork nature and inefficient character of the book made it unworthy to be approved by the Council. The omissions, too, of which many were instanced, were serious and numerous, and he urged the revision so essential to the work. A permanent committee, he thought, should be appointed to superintend the Pharmacopœia.

Dr. ANDREW WOOD said a Pharmacopœia committee existed. Many of the omissions were not important. It was dangerous to continually change nomenclature. The existing committee would consider what had been said. He saw no reason for the motion.

Mr. MACNAMARA said he had resigned his position as a member of the Pharmacopœia committee because he had never been summoned to attend a meeting.

Dr. QUAIN defended the Pharmacopœia. It was impossible to please everyone. It was better to retain the old nomenclature than change it with changes in scientific chemistry. Five thousand copies of the Pharmacopœia had been just ordered by the executive committee.

Dr. AQUILLA SMITH thought it might be wise to consider the advisability of revising the Pharmacopœia two years hence.

Mr. MACNAMARA said the production of such a work demanded years of labour; should not be done quickly. He did not want a new volume immediately, but only the appointment of a committee to enter on the important work.

After considerable further discussion a Pharmacopœia committee, to the surprise of the Council, was found to exist, and the motion, then shown to be an improper one, was withdrawn. The committee consists of Drs. Quain, Pitman, A. Smith, Haldane, and Mr. Macnamara.

Certain communications in regard to attendance on lectures, submitted to the General Council by the executive committee, were taken as read, and

Dr. HAUGHTON thought that the Carmichael School deserved credit for enabling students to qualify for medical practice by attending evening lectures, and he moved that the Medical Council does not see reason to object to the proceedings of the Carmichael School directors who sanctioned these evening courses, and desired the opinion of the Council on them.

Dr. ROLLESTON moved and Dr. PYLE seconded an amendment that the Council approve of the action of the R.C.S.I. in condemning the evening lecture system.

Mr. SIMON said it would be grossly unfair to place any restrictions on the way in which students obtained their information.

Dr. SCOTT ORR supported the amendment, which was objected to by Dr. AQUILLA SMITH.

Dr. PETTIGREW spoke in favour of Dr. Rolleston's amendment.

Dr. HAUGHTON having spoken in reply, saying that the Carmichael College had been forced to the course they took rather than issue false certificates, the amendment was put to the vote, and lost, and the original motion carried by a large majority.

Communications were then read in regard to certificates of attendance on lectures—viz., a letter from the Branch Council for Ireland, enclosing a report on the alleged issue of certificates without attendance by a Dublin school of medicine; and also the following resolution passed by the General Medical Council, July 19, 1879: "That the Branch Council for Ireland have its attention drawn to a statement made by a member of this Council, to the effect that certificates of attendance have been issued in a Dublin school to students who have not given such attendance, and that the Branch Council be requested to inquire into this matter, and to report thereon to this Council at its next meeting."

Dr. HAUGHTON moved "That the General Medical Council are of opinion that no medical authority should receive a certificate of attendance upon lectures or hospitals, unless such certificate state the actual number of attendances made by the holder, and the total possible number of attendances." This he was led to by the consideration that the resolution of July 19 did not include all the cases. Certificates that carried no guarantee of attendance were notoriously issued by certain schools in Ireland. The action of the Branch Council for Ireland in relation to the alleged malpractice brought out the truth that this existed to a considerable extent. Replies to inquiries as to the means of certifying attendance at lectures, were in some cases eminently unsatisfactory, but in others sufficiently satisfactory. He asked permission to withdraw the second division of the motion, which specified a minimum attendance at fifty per cent. of lectures.

Prof. TURNER seconded the motion.

Dr. A. SMITH endorsed the statement of the abuses complained of by Dr. Haughton.

Dr. ROLLESTON pointed out that the Council could control examinations, but not lecture attendance; and he urged that such resolutions as that proposed were simply illusory. The reason for lectures is less now than when books were much dearer, and notes of lectures served their purpose.

Sir JAS. PAGET agreed with Prof. Rolleston that to carry the motion would be to retrogress. It would command bodily attendance, when mental appreciation of the subject matter of the lectures could not be ensured. The schools he pointed out did not sign certificates for *attendance*, but only when students passed satisfactory test examinations. The whole argument for the motion was based on the dishonesty of certain schools in Dublin.

Dr. HUMPHRY objected to the principle of the motion.

The motion was lost.

Mr. SIMON moved, "That the Council beg leave to bring under the particular notice of her Majesty's Government the position in which the question of legislation for the medical profession was left standing at the time when the late Government retired from office, and respectfully submit to her Majesty's Government that, in the opinion of the Council, it is essential for those important public interests which are involved in the good ordering of the medical profession that her Majesty's Government should at their earliest opportunity consider and determine the course which they will advise the Legislature to follow with a view to terminate a period of indecision and unsettlement which is most injurious to the progress of medical education."

Dr. QUAIN seconded the motion.

Dr. A. WOOD moved the previous question, giving as a reason the assurance conveyed by Mr. Mundella that Government are considering the question.

Dr. PYLE seconded the amendment.

Mr. SIMON said with much regret he had to say that he had felt very much the impropriety of the Council sitting in deliberation pending the settlement of its existence. Prospective recommendations as to medical education would only be out of place so long as a mere political accident prevented the laying of regulations before the Council regarding its own constitution. The Royal College of Surgeons had been deterred from any considerable movement by the uncertainty of medical affairs, and the same could be said of all the other great corporations. He would remind Dr. Wood that it was due to him a parliamentary select committee was appointed. The final report of that committee has been delayed by the change of parties, and it was incumbent on the Council to do its best to aid a solution of the question as far as possible, and it should beseech Government aid in the matter. The Council could exercise no real influence in the present state of affairs while the question of its constitution is *sub judice*.

Dr. QUAIN contended it was the duty of the Council to demand Government to afford it an opportunity of meeting the accusations brought against it, and he therefore seconded the motion.

Mr. MACNAMARA thought it wanting in courage to adopt such a course as Dr. A. Wood proposed. He thought Mr. Simon's resolution a most proper one.

Dr. ROLLESTON believed Government interference a grievous evil, and he could not support the motion.

Dr. PYLE thought it would have been better had no expression of opinion been evoked from the Council.

Dr. HAUGHTON defended the motion.

The PRESIDENT having briefly spoken,

Dr. HUMPHRY said he must vote against the motion, because he preferred the ills we have to those we know not of. The motion asked for legislation, which was not required or desirable.

Dr. A. WOOD begged leave to withdraw his amendment, and to move that the question be not put, which being seconded,

Mr. SIMON replied to the objections against the motion, that in 1877 the late Government took action on the sug-

gestion of the Council, with which it was in constant communication. It would therefore be preposterous to pretend fear of Parliament now. He asked only for *settlement* and the removal of uncertainty.

On the amendment being put, it was carried, the original motion being thereby lost.

Mr. BRADFORD moved, "To submit to the General Council a communication from the Apothecaries' Society of London, relative to certain evidence which has been given before the House of Commons Select Committee on the Medical Act (1858) Amendment Bill."

Dr. PYLE seconded the motion.

Dr. PITMAN moved as an amendment, "Inasmuch as the evidence given before the Select Committee of the House of Commons in 1879, on the Medical Act (1858) Amendment Bill, was not given by any one under the authority of, or on behalf of, the General Medical Council, it would be improper for the Council to receive any statement in correction of that evidence."

This course Dr. Pitman took, because he thought it unnecessary that all communications addressed to its President should be submitted to the Council generally, and no paper dealing with the Parliamentary discussion in the Council should be entertained by the Council.

Standing orders having been suspended, the Council continued its sitting to complete the business before it.

Dr. STORRAR thought it an arbitrary proceeding to suspend standing orders on the vote of a majority.

The PRESIDENT said he had received the letter referred to, as he had received many communications which he would be sorry to be compelled to lay on the Council table.

Dr. A. SMITH thought it absurd to vote concerning a communication of which they know nothing.

DR. QUAIN thought the object might be obtained by sending copies of the documents to all the members of Council.

By the consent of the Council both motion and amendment were withdrawn.

Sir JAMES PAGET seconded the motion.

Mr. SIMON opposed the motion on the ground that the uncertainty surrounding the stability of the Council made it undesirable.

Dr. QUAIN supported the motion.

Dr. A. SMITH considered it was the duty of the Council to renew the visitations.

Dr. HUMPHRY said the executive committee should direct the visitors to ascertain the causes of rejections of so large a number of candidates.

The motion was carried.

Dr. HUMPHRY moved that the executive committee shall instruct the visitors to make inquiries into the causes of rejection of candidates.

Dr. HAUGHTON doubted whether the rejections were as numerous as assumed.

Dr. FERGUS seconded the motion, which was carried.

After some formal business had been transacted, the Council terminated its sittings for the session.

AMONG the workers in the St. Gothard tunnel frequent cases have occurred of the development of anguillules, anchylostomes and other internal worms hitherto very rare. This is supposed to account fully for the anæmic condition into which many of the men got.

THE death-rate last week from the seven principal zymotic diseases per 1,000 in the large towns ranged from 1·4 and 1·9 in Wolverhampton and Brighton, to 5·9, 7·8, and 7·9 in Salford, Dublin, and Norwich. Scarlet fever showed the largest proportional fatality in Norwich, Sheffield, Sunderland, Dublin, and Salford; measles in Leicester, Oldham, and Sunderland; and whooping-cough in Norwich, Liverpool, and Bradford. Small-pox caused 4 more deaths in London, 10 in Dublin, one in Birmingham, but not one in any of the other large towns.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, JULY 21, 1880.

THE GENERAL MEDICAL COUNCIL AND THE GOVERNMENT.

THE most important motion brought before the General Medical Council during its recent session was unfortunately deferred for consideration till the last sitting, and, as might almost have been predicted from the previous expression of feeling on the subject, by individual members of the assembly, it received but scant treatment, and was shelved with the fatal complacency which distinguishes the assembly entrusted with a legislative function over the medical profession. In the present unsatisfactory state of affairs that have relation to the stability of the Council, in view of the uncertain tenure of its existence, and in the knowledge it possesses of the all but universal dissatisfaction its proceedings have created, it might have been expected that any means of determining the base on which its future operations must depend would have been eagerly seized and made the most of. It was therefore with reanimated hope that its well-wishers saw the announcement of a resolution standing in Mr. Simon's name, to the effect:—

"That the Council beg leave to bring under the particular notice of her Majesty's Government the position in which the question of legislation for the medical profession

was left standing at the time when the late Government retired from office, and respectfully submit to her Majesty's Government that, in the opinion of the Council, it is essential for those important public interests which are involved in the good ordering of the medical profession that her Majesty's Government should at their earliest opportunity consider and determine the course which they will advise the Legislature to follow with a view to terminate a period of indecision and unsettlement which is most injurious to the progress of medical education."

The crying necessity for some such action as this, and the importance of settling, as soon as may be, the footing on which legislation on behalf of the medical profession is to be conducted in the future, served to assure the reflecting that the above motion would receive all the attention its importance merits. Whether it was, however, that the adequate discussion of it was deemed to demand a larger share of the time and funds of the Council than could be spared to it after the protracted debate on preliminary education, or that the feeling of boredom had been too sufficiently aroused by the same means, certain it is that, spite of an earnest appeal from the framer of the motion, it was pooh-poohed, and straightway relegated to the wasteful heap of rejected resolutions, already ominously big for the occasion. Well would it have been could the General Medical Council have appreciated the magnitude of the issue at stake: it might then have applied to itself the well-worn warning *veniente occurrite morbo*, and by showing some interest in things, not perhaps strictly within the narrow limits which bound its surroundings, yet still of vital import to its own well-being, have aroused a sentiment that would counterweigh to some extent against the mistrust it has unfortunately excited.

The effect produced on those outside the Council by this hasty refusal to make or solicit inquiry concerning ts constitution, and to request a speedier settlement of the unsatisfactory laws by which the practice of medicine is regulated in this country, is one that will not speedily be effaced. Disappointment, keen and lasting, is the distinguishing characteristic of the feeling, and to what results it is destined to lead, it were impossible as yet to determine. One point is certain, the opposition to the conjoint scheme, ascribed again and again with so much bitterness to the Scotch Corporations, has become the fault of every member of the Council except the small minority that supported Mr. Simon's attempt to re-introduce the question of medical reform. True it does not take the specific form of objection to a particular scheme, but the consequence of the total rejection of a suggestion to hasten a Parliamentary solution of the vexed subject, can only be to delay the enactment of any laws having in view the consolidation of examinations. It cannot be urged that Mr. Simon has been guilty of an improper or ntoward proceeding. His was no more that a modest pplicati on to the present Government to resume the labours efficiently commenced by its predecessor, and the most exacting apologist can see in the words of the motion nothing to shock either the most sensitive or the most advanced advocate for improvements in the degenerate system of to-day. The opinions of a simple dissenter, however strongly he may insist on them, can have little weight when to them is opposed a self-satisfaction that is doomed to disappear before their acceptance. This, though it is a mournful truth, is the real explanation of the action of the Council in respect to Mr. Simon's motion. Unfortunately, perhaps, but with a manly willingness to face the humiliating weakness it exposed, Mr. Simon declared the folly of which the Council had been guilty in framing new recommendations while it had no satisfactory assurance that even one of them would live to become a guide for those they were intended to influence. The blindest admirer of the combined excellencies of the General Medical Council is unable to disguise the possibility it labours under, that ere another year has passed, that something may happen to render nugatory all that has been accomplished after nine day's disputation and an expenditure of eighteen hundred pounds. This unpalatable statement was so evidently distasteful, as proved by the angry mutterings with which it was received, that Mr. Simon must have felt how little could be hoped for from that which ought to be the *fons et origo* of suggestions for reform. The bane of the Medical Council is its inveterate hatred of anything approaching to a revelation of its own weakness; and the rooted belief, never so transparently evidenced as it was last week, it has in its own immaculate perfection. Until it shall have outgrown these two faults, and is content to learn how it can be wise and wiser yet, there is little but disappointment and disaster in store for it. It should have no fear of an early settlement of the question which it assumes the credit of introducing to the consideration of Parliament. It possesses champions within itself ready and able to defend its pretensions; and it ought not, therefore, to be slow in responding to a call, whencesoever it emanates, to put its house in order, and look about for other rooms to dust.

There is every probability that more than one of the crude recommendations that will be the outcome of the past session's work, will meet with only contemptuous ignoring from many of the bodies they are to be addressed to, and in the opposition likely to arise therefrom will be an earnest of what will be a fruitful source of discussion should the attempt now made to impede Parliamentary legislation be unfortunately successful.

SUNSTROKE IN INDIA.

Our readers, more especially those who have served, or are now serving, in India, have no doubt read with interest the papers on the above subject written by Surgeon-Major Curran that have during the last few weeks appeared in the pages of this journal. Although undoubtedly the affection so-called occurs as a direct result of exposure to the sun, this is by no means a necessary result of such exposure, even in the north-west of India, where, for at least a couple of months at a time, the hot winds prevail with an intensity not to be realised by any except those who have actually experienced them. Troops marching during the daytime are peculiarly liable to be seized with the affection, as was on various occasions painfully illustrated during the Mutiny campaign, and accounts are still fresh in our recollection of how, during the long and fatiguing marches of that time, soldiers and officers alike found it necessary, as a protec-

tion against *sunstroke*, to have their persons, as they stood in their clothes, completely *soused* with water from time to time, the water for that purpose being carried in skins by bullocks and camels. On the other hand, *individuals* whose avocations lead them much out of doors, even in northern India, and sportsmen who thus expose themselves for pleasure, do not necessarily suffer in this way so long as they avoid indulgence *beyond* moderation in spirits or in beer.

But more liable than these to attack by *sunstroke* are certain classes who least expose themselves to the sun, and in whom therefore the disease is with more propriety known as heat-apoplexy. The persons who are thus included are those who are of inactive habits, who indulge in "drink" and in sleep to an extent beyond moderation, who pass much of their time in hospitals, or in the guard-room. Among these the attack usually comes on in the latter part of the day, or during the night, and so insidiously as only to be noticed when it has become developed, perhaps beyond remedy. During the hot dry weather it frequently supervenes upon a debauch; but the remark has been made that the disease only occurs when the temperature in the shade exceeds 97° F., and aqueous vapour in the atmosphere is under 50. Then, again, notwithstanding the views to the contrary expressed by Surgeon-Major Curran, there is the testimony of many experienced observers, and also of men whose "learning" scarcely deserves his comments in his *note*, No. 60, to the effect that the difference between sunstroke, heat-apoplexy, sun-fever, heat-fever, or ardent fever in India, is of degree rather than of nature; and that cases of "fever," however designated, pass often and readily into the more severe and fatal condition of heat-apoplexy, is a fact well known to the majority of Indian medical officers.

Hitherto treatment of heat-apoplexy, except in the very early stages of the attack, has been only in a very slight degree successful. Dr. Curran quotes extensively from papers on this subject by Mr. Hill, of the Bengal Medical Service, and the pity is that the views of the latter are not now more generally known in India than they appear to be. Briefly he prescribes the douche to head and epigastrium, leeches to temples, free and rapid purgation (not by turpentine) and counter-irritation. But what is done must be done quickly if the patient is to be saved at all.

Notes on Current Topics.

The Beginning and End of a Medico-Advertising Embassy.

A FILE of Melbourne newspapers which has reached us within the last week supplies us with the expected *dénouement* of the triumphal progress of a certain Dr. Beaney, whose visit to the United Kingdom, and especially to Dublin, last autumn, was the theme of somewhat lively discussion at the time. This gentleman arrived from the Antipodes heralded in every *buyable* newspaper as a bright and shining light in surgery, a commissioned representative of the Victorian Government, and an embodiment of every virtue, social and professional. After a very brief—and, we hear, rather barren—visit to London, Dr. Beaney reached Dublin, where his paragraph puffs at once attracted notice, and he would, no doubt, have succeeded in getting himself recognised by a considerable number of the profession but for certain rumours as to his professional antecedents which filled the medical air. People began to talk of a certain prosecution in connection with the death of one Mary Lewis, which occurred in Melbourne some years ago, and a telegram was handed about in Dublin sent by the Victoria Medical Society from Melbourne, which emphatically repudiated the honour of association with Dr. Beaney. It was also hinted that the authoritative commission from the Victorian Government which this gentleman asserted that he possessed had been positively refused to him, and that he had been obliged to content himself with a simple private letter from one member of the said Government.

Much more chatter of this sort passed from mouth to mouth in Dublin at the time, but as it seemed to be discordant with the solid facts that Dr. Beaney had plenty of money—could pay for any number of the best dinners for those who would accept his hospitality—and had ready—if not gratuitous—access to the editorial columns of certain Dublin papers, and one of the London 'society" journals, a certain number of medical men in Dublin (a few of them being influential and representative) were found willing to patronise the Antipodean ambassador, and were repaid for their easy virtue by reading their names almost every day in the numerous paragraph advertisements of Dr. Beaney and his dinners. As is always the case, those who declined to join the entertainments, or who expressed their doubts as to Dr. Beaney's merits, were denounced as the calumniators of injured virtue, and though their warnings had the effect of causing certain much-coveted medical honours to be withheld from the lion of the day, they had to bear the full measure of unpopularity which always is the lot of censorious and suspicious people.

Well, Dr. Beaney went back to Melbourne, and at once a rumour reached Dublin that if we would only, as the Scotch say, "bide a wee," we should hear all about the medical embassy and its hero. The *bonne bouche* thus promised we have before us in the shape of an action taken by a certain medical publisher in Melbourne against the honoured of Dublin to recover £650. For what? Well, here are the items:—£400 as a bribe to said publisher for getting from the official who gave it, the letter which Dr. Beaney called his "commission;" £50 for finding two authors to write the books published and advertised by Dr. Beaney as his own; and £141 for printing, as an advertisement, 800 copies of a stupendous gilt auction catalogue of that gentleman's property, sold off on his leaving for Europe. We regret that we cannot afford our readers—and especially those gentlemen who have acquired a special interest in the matter by participation in Dr. Beaney's hospitalities—the amusement which we have ourselves enjoyed in reading the unfolding of the whole affair. Suffice it to say that, on the evidence of the learned doctor himself, it was established that he never had had—but had been point-blank refused—the commission which was his ticket of admission to Dublin society; that what he had in the way of a letter he paid

for in hard cash to a local stockbroker, who got it by importuning the official who gave it; that he really did not write a line of the books which he published, and the lectures which he delivered as his own; and lastly, that he had plainly and simply purchased the laudation of the London and Dublin papers who befriended him by the gift of valuable diamonds and other articles which sub-editors like to have. We are doubly sorry that our space will not enable us to publish the report of the trial, because we feel that it would be instructive reading, if only as a warning to those who, with excessive good nature, but insufficient caution, fulfil their duty to the stranger by eating his dinners and speaking his praises.

Chelsea Hospital for Women.

On Friday last the Princess of Wales laid the foundation stone of a new hospital to be erected in the Brompton Road for the treatment of women's diseases. About ten years ago a dispensary was started near the present site, on a small scale, and a few beds were opened for the reception of gentlewomen in reduced circumstances, as well as for the treatment of out-patients. The applications for admission soon became too numerous to find accommodation, and in place of spending money in patching up old houses, it was wisely determined to make an appeal to the public for support, and provide a proper hospital. This may seem a somewhat bold project, especially when we hear lamentations of the closure of beds and wards taking place in several old-established hospitals, simply from want of funds. Notwithstanding, we believe it will be found to be wiser to provide extended accommodation for outlying districts than to keep beds going within the small inner circle of this vast metropolis. In the case of women, too, suffering from certain distressing kinds of disease, the hardship of having to tramp long distances is very much greater than it may at first sight appear, whilst it also necessitates a serious loss of time in overcrowded, unwholesome waiting-rooms.

Brompton and Fulham will now be more amply hospitalled, and of a more varied character than that of most other parts of London; and Friday will be remembered as quite a red-letter day amongst the inhabitants. Their Royal Highnesses were punctuality itself; two of their Royal children accompanied them, as well as a goodly retinue of lords and ladies gaily dressed. Outside the marquee a guard of honour of the Queen's (Westminster) Rifle Volunteers was drawn up, whilst the inside was thronged with visitors. Their Royal Highnesses were received by the President, the Earl of St. Germans, and the officials of the institution, by whom they were conducted to the daïs where the stone was to be laid. A pleasing incident was the acceptance by the Princess of a bouquet of flowers, the gift of the in- and out-patients of the hospital. Upon entering the building the Royal party were greeted with the strains of the national anthem, sung by the choirs of various neighbouring churches. The Lord Bishop of London having offered up prayer, the Earl of St. Germans read an address of welcome to her Royal Highness, in reply to which the Prince of Wales said:—"I am desired by the Princess to offer you her acknowledgments for the address which you have just read to h r, and to express her gratification at the statements contained in it regarding this hospital, and to assure you that it gives her very great pleasure to be here to-day to take part in this ceremony. We cannot conceive an object more worthy to be taken up, or more likely to be of great benefit to a suffering class in this country. Again assuring you of the pleasure it gives us to be here, we willingly give our consent to your naming two of the wards of the new hospital the Alexandra and the Albert Edward." The choirs then sang a hymn specially composed for the occasion by Mr. Arthur Sullivan, after which the treasurer read the record of the proceedings, which, placed in a glass case with one of the hospital reports, a photograph of the building, and some coins of the present year, was placed beneath the foundation stone. The Princess of Wales then performed the ceremony of the day, after which upwards of a hundred ladies and children placed purses before her Royal Highness, who gave each of the donors a most kindly and gracious recognition, and the ceremony was brought to a close by the Bishop of London pronouncing a benediction.

A Medical Murder.

Under this heading the *Paddington Times* relates an occurrence which, without explanation, is simply incomprehensible. A medical man, called to attend a patient suffering from bronchitis, is declared to have deliberately killed the unfortunate victim by applying, first, a handkerchief saturated with chloroform to his face, and subsequently, on the remonstrance of the patient's son, a napkin on which had been poured a mixture of ether and ammonia. Heart disease having been diagnosed, the latter stimulant might have been intended to produce a beneficial effect, as, indeed, the doctor declared had been his hope; but the extraordinary part of the revelation is in the fact that he expressly admitted to the wife of the patient not only that he had purposely destroyed her husband's life, but that she ought to be grateful to him for doing so; and added further that he thus treated all his patients who were great sufferers. Our lay contemporary, with some reason, concludes that the author of this diabolical outrage is a madman. If the account be true, and it is given in a way that carries conviction, it constitutes an entirely unheard-of departure in the paths of malpractice. That any medical gentleman can be guilty of anything of the kind is, however, very difficult to believe, and pending a searching inquiry into the facts of the case, it will be wiser, as it is certainly preferable, to hope that an explanation of the whole matter will be forthcoming. There should be no delay in settling the matter satisfactorily one way or another, for the credulous public, too willing to accept sensational statements, will not be slow to approve this argument in favour of a not altogether exploded notion that medical men do sometimes treat their long-suffering patients to that which will effectually and for ever cure them of all pain.

Bronze Poisoning.

A case of poisoning by metallic copper has recently been investigated in the East end of London, and the evidence adduced proves conclusively that the occupation of "bronzing," on which deceased had been engaged, is detrimental, and may even prove fatal to human lives.

The inhalation of the copper powder for a length of time results in its being deposited in large quantities in the tissues and organs of the body, and the well-known dangers attending this form of poisoning should tend to the enforcement of rules for securing the safety, as far as possible, of those engaged in this branch of labour. Mr. C. M. Tidy, M.B., public analyst, gave evidence at the coroner's inquiry, and recommended the observance of the precautions suggested by Dr. Ballard under similar circumstances, such as the wearing of respirators while working with the metallic powder, careful washing at the end of the work, and the use of a special dress during it, strict cleanliness; and, especially the use of copious draughts of milk to act as an antidote to the poison. The unfortunate accident to which the deceased youth owed his fate is not by any means a singular one, or without numerous repetitions, although they may not be so prominently noticed; and it ought to lead to official interference so far as to insist on the unceasing observance of precautionary measures.

Student Thieves.

For a long period of time there have been occasional instances of theft by medical students reported from the different hospitals and schools, both in London and the provinces. Guy's, the London, Charing Cross, St. Mary's, Manchester, Leeds, Birmingham, and many others have been the scenes of these petty depredations, and in the majority of instances the culprits have been students at one or other of the great centres of medical education. The latest addition to the list is St. Bartholomew's, a student of which school is now under remand, charged with the commission of a large number of thefts from his fellows. The reflections to which these unhappy disclosures lead are by no means comfortable. They tend to prove the truth of the statement made to the effect that there is a certain and possibly not inconsiderable number of young men who register as medical students, and who are morally unfit to become members of an honourable profession. Whether it is that these unfortunate youths are led into temptations which necessitate their extricating themselves from pressing difficulties by actual dishonesty, or whether criminal by inclination, they sink deeper and deeper into ruin, the fact nevertheless remains that a certain worthless residue does exist, and how to eliminate it and destroy its damaging effects must be one of the problems to be solved by the reformers of the future.

Dr. Stevens's Hospital, Dublin.

The correspondence columns of the Dublin papers have re-opened the discussion of the proceedings of the Board of Governors of Dr. Stevens's Hospital last February. It will be recollected that in appointing two physicians to the hospital they passed over a working member of the medical school attached to the hospital, who had served the institution well and zealously, and appointed in his place a young gentleman who had never had responsible public charge of a sick person in his life. It will be recollected that several of the leading members of the hospital and school staff marked their indignation at this unmerited and extraordinary slight to their colleague by resigning their connection with the hospital. Since then, and in consequence of the retirement of these gentlemen, the school has collapsed, and we believe that the portion of the Government grant which was allocated to school purposes has been withdrawn, and thus Dr. Stevens's Hospital, which was once one of the finest clinical hospitals and educational institutions, has, by the arbitrary act of a clique of laymen, been lowered to the level of an unknown and unregarded subsidised establishment. We suppose that the lay governors of the hospital are pleased with, and proud of, their work. If not, we do not know anyone else who is likely to be so. The transaction forcibly illustrates the amount of consideration which the interests of an hospital receive whenever the stimulus to perpetrate a job weighs in the opposite scale.

The British Association for the Advancement of Science.

The arrangements for the fiftieth meeting of the British Association, to be held at Swansea, are as follows:—

The first general meeting will be held on Wednesday, August 25th, at 8 p.m. precisely, when Professor G. J. Allman, M.D., F.R.S., Pres. L.S., will resign the chair, and A. C. Ramsay, LL.D., F.R.S., Director-General of the Geological Survey of the United Kingdom, and of the Museum of Practical Geology, President Elect, will assume the Presidency, and deliver an address. On Thursday evening, 26th, at 8 p.m., there will be a *soirée*; on Friday evening, 27th, at 8.30 p.m., a discourse by Professor W. Boyd Dawkins, F.R.S., on "Primæval Man;" on Monday evening, 30th, at 8.30 p.m., a discourse by Francis Galton, M.A., F.R.S., on "Mental Imagery;" on Tuesday evening, 31st, at 8 p.m., a *soirée*; and on Wednesday, September 1st, the concluding general meeting will be held at 2.30 p.m.

On Saturday evening, 28th, Henry Seebohm, Esq., F.Z.S., will deliver a lecture to the operative classes on "The North-East Passage."

Amongst the Sectional officers are the following:—

Chemical Science. President—John Henry Gilbert, Ph.D., F.R.S. Secretaries—Harold B. Dixon, F.C.S.; Dr. W. R. Eaton-Hodgkinson; P. Phillips-Bedson, D.Sc.; and J. M. Thomson, F.C.S.

Biology. President—A. C. L. G. Günther, M.A., M.D., F.R.S. Secretaries—G. W. Bloxam, M.A.; Professor M'Nab, M.D.; John Priestly; and Howard Saunders, F.Z.S.

Economic Science and Statistics. President—George Woodyatt Hastings, M.P. Secretaries—Noel A. Humphreys, F.S.S., and Constantine Molloy.

The Metropolitan Asylum.

On Saturday last the managers of the Metropolitan Asylums District concluded their annual visitation to the various institutions under their control by an inspection of the asylum at Caterham, which, like its sister institute at Levesden, contains a population of something like 2,000 persons belonging to metropolitan parishes on the Surrey side of the river who come under the designation of imbeciles. The company, which included Dr. Brewer, the chairman, and most of the managers, with Mr. W. F. Jebb, their secretary, and a number of gentlemen inter-

ested in Poor-law administration, inspected the stores, bakery, kitchen, laundry, chapel, and workrooms, where the inmates are employed in various trades of a useful and productive character. Both the male and female wards and dormitories were also inspected, and the appliances for the comfort and extreme cleanliness of every department were the theme of general approbation. In the course of his remarks, the chairman of the committee referred to the fact that a very large proportion of the clothing and the whole domestic work of the establishment were made and performed by the inmates, whilst the agricultural produce of the land contributed largely to the supply of the food they required. Indeed, economy combined with efficiency was the principle upon which the whole of the arrangements were conducted, and taking into consideration the position of the inmates, the general health of the institution was excellent.

Death from Chloroform.

A CASE of sudden death from the inhalation of chloroform is recorded in the *Canada Lancet*, of July 1, 1880. The patient, Catharine Donahue, had been taken from the House of Refuge after her accouchement to the City Hospital, Hamilton, Ont., for the treatment of an abscess of the breast, and the medical evidence showed that she had only taken a few inspirations of the anæsthetic when she became insensible, and all endeavours to resuscitate her were in vain. The post-mortem examination proved that all the organs of the body were in a healthy state, and that death resulted from the administration of chloroform. The jury returned the following verdict :—"That Catharine Donahue came to her death on the 3rd day of June, 1880, from chloroform administered in the Hamilton City Hospital, and it appears to this jury that the chloroform was administered in a proper manner, and her death could not have been foreseen, and no blame can be attached to any one."

The Public Health (Ireland) Amendment Bill.

MR. REDMOND'S Bill for the amendment of the Public Health (Ireland) Act, 1878, which is now before the House, is of no interest to the medical profession. It simply empowers the Local Government Board on the application of an urban sanitary authority to enlarge any existing provisional order, notwithstanding that it was obtained previous to the passing of the Act of 1878. Under the previous Act a great injustice was inflicted on the town of Wexford last year by the absence of any power to extend a provisional order passed three or four years ago, and Mr. Redmond's Bill, which is pretty certain to pass without any opposition, will relieve the Town Commissioners in this as well as many other towns in Ireland.

Metropolitan Hospital Sunday Fund.

IT is with much satisfaction we are able to announce the fact that the amount collected on Hospital Sunday, and paid in to the Treasurer of the Fund, exceeds that of other years by several thousand pounds. Up to the time of going to press, and with other amounts yet expected to come in, over £30,000 have been received. This will be considered as a very gratifying result. At the same time we sincerely regret to have to record the death of one of the earliest and most earnest promoters of Hospital Sunday, the Rev. Canon Miller, Vicar of Greenwich.

Treatment of Lunatics in France.

IN a recent criminal trial in France, in which a lunatic, after having had his arm broken by a *chef de culture*, under whom he was placed, and who afterwards strangled him and buried his body, the unpleasant fact came out on the trial that the lunatics at Clermont are struck and beaten by sticks or whips by those who have charge of them. Dr. Labitte, who is the medical officer, is not the director of the Clermont Asylum.

Potable Sewage.

THE Guardians of the Newcastle West Union, in the county Limerick, have been informed by Dr. Cameron, the county analyst of that district, that the water which is consumed by the population of Newcastle West is nothing better than "sewage slightly diluted."

ONE of the summonses against Mrs. Rutley, of Wandsworth, for illegally receiving lunatics without a licence, referred to in our last, has been withdrawn.

DR. ARNOLD BEER, a medical and scientific writer of some celebrity, died somewhat suddenly at the Grand Hotel, Paris, on Tuesday, at the age of forty-five.

THE Government promised, in the House of Lords on Friday, that the Noxious Vapours Bill and the Report of the Royal Commission thereon, would be one of the first subjects to be dealt with next session.

THE title of the essay to which the Howard medal of the Statistical Society will be awarded in November, 1881, is "On Gaol Fever, from the earliest Black Assizes to the last recorded outbreak in recent times."

THE annual summer *fête* of the inmates of the Earlswood Asylum for Idiots took place on Friday last. The total expenditure for the year in carrying on this institution was stated to be £27,500. The number of inmates is 562.

IT is understood that the Report of the Committee on the Naval Medical Service will be presented to the Admiralty during the present week. It is, therefore, yet possible that the new Warrant may be promulgated before the 9th proximo, the date of the next examination for medical candidates for the naval service.

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 17, Bombay 29; Paris 23; Geneva 18; Brussels 24; Amsterdam 26, Rotterdam 21, The Hague 18; Copenhagen 23; Stockholm 27; Christiania 20; St. Petersburgh 50; Berlin 42, Hamburg 24, Dresden 27, Breslau 36, Munich 38; Vienna 23, Buda-Pesth 36; Venice 25; Alexandria 50; New York 23, Philadelphia 19, and Baltimore 31 per 1,000 of the populations. Small-pox caused 58, measles 38, and typhoid fever 24 deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

GLASGOW OPHTHALMIC INSTITUTION.—The annual distribution of prizes to the successful students attending the Glasgow Ophthalmic Institution took place on Tuesday, the 13th inst., in the class room of the Ophthalmic Institution, 126 West Regent Street. There was a full attendance of students. Sir James Watson presided, and along with him were Dr. Wolfe, the Rev. Dr. Marcus Dods, Mr. J. C. Wakefield, Mr. James White, of Overtown, and Dr. J. G. Wilson. This Institution is a very flourishing one. Perhaps of all the institutions in Glasgow of a similar nature there is none so well managed as "the Ophthalmic;" and its statutory appearance in print is almost certain to afford flowers of speech for which the public and the profession cannot fail to be duly grateful. The venerable and esteemed chairman delivered a brief address, in the course of which he remarked that "the eye was one of our most valued senses, but it was one most easily injured; therefore he was glad that young men were being trained in a science which up till lately was left in the hands of *individual country surgeons*," and here we are told "applause" came in. Dr. Wolfe, we are informed, "had introduced this year an additional subject—namely, *performing operations*;" and he also was rewarded with the applause to which his feat undoubtedly entitled him. Mr. Wakefield, who is an authority on all subjects, tells the public that "*he* considered Dr. Wolfe far in advance of anyone *here or elsewhere*"—no mean boast certainly. Mr. Beck pointed to Dr. Cluckie's appointment to the Greenock Infirmary "as a proof of Dr. Wolfe's eminent abilities as a teacher and an oculist;" the fortunate Dr. Cluckie being a former assistant of the eminent Dr. Wolfe. Singularly enough this extravagant personal laudation is a thing which does not find place in the reports, or at the meetings of other kindred institutions in Glasgow, and it is surely legitimate to ask whether they are in good taste as appearing in the public newspapers, or relevant to the proper management of the Institution.

COMRIE.—MONUMENT TO THE LATE DR. LEITH.—The parishioners of Comrie have erected in the new cemetery a handsome monument in memory of the late Dr. Leith. The structure is in form of an obelisk, stands 13 feet high, and is of Peterhead granite. The sculptor was Mr. Beveridge, Perth.

DUMBARTON.—Dr. Richard has been appointed medical officer of health for the Burgh.

REGISTRAR-GENERAL'S RETURNS.—According to the weekly return of births, deaths, and marriages for the eight principal towns of Scotland, the death-rate for the week ending with Saturday, July 10th, 1880, was 20·4 per 1,000 of estimated population. This rate is 0·4 above that for the corresponding week of last year, and 0·5 below that for the previous week of the present year. The lowest mortality was recorded in Leith, viz., 13·3 per 1,000, and the highest in Paisley, viz., 25·5 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·9 per 1,000, being almost the same rate as that for the previous week. A decrease occurred in the number of deaths from measles, while in scarlet fever and diseases of the bowels there was a considerable increase. A female, said to have been veccinated, died in Glasgow from confluent small-pox. There was no visible mark of vaccination.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 10th inst., the deaths in Edinburgh fell from 93 to 80. The death-rate was 19 per 1,000. The zymotic mortality amounted to 9. There was only 1 death from fever, and that was reported from the southern suburbs.

MORTALITY OF GLASGOW.—The mortality in Glasgow during the week ending with Saturday, the 10th inst., was at the rate of 23 per 1,000 of the population annually. In the corresponding seven days of 1879 the deaths were at the rate of 22 per 1,000.

EDINBURGH UNIVERSITY COURT.—At a meeting of the Edinburgh University Court, held on the 16th inst., *inter alia*, Mr. James Hunter, F.R.C.S. Edin., was recognised as a teacher of medicine in Edinburgh whose lectures on the Institutes of Medicine should qualify for graduation in Medicine in the University in terms of Ordinance No. 8, sec. 6 (4).

INDIAN ITEMS.

MEDICAL SERVICES IN AFGHANISTAN.—Sir Donald Stewart writes in his despatches regarding the action at Ahmed Khel, near Guznee, that "the arrangements for the immediate care of the wounded reflect the highest credit upon Deputy Surg.-Gen. A. Smith, C.B., the principal medical officer with the force; and the exertions of the subordinate medical staff deserve my warmest acknowledgments."

A LADY DOCTOR.—Miss Dora White, a graduate of the Madras Medical College, and the Resident Medical Subordinate of the Military Female Orphan Asylum, who recently proceeded to Bhrig, Cutch, to attend on her Highness the Maharani of Cutch, has returned to Madras, after having successfully treated the Maharani, whose failing health had given occasion for some anxiety. Miss White's services obtained for her the special thanks of her Highness the Maharani's family.

LIFE AND DEATH.—This is the substance of a review of a book just published on the "Destruction of Life by Snake-bites, Hydrophobia, &c., in Western India":—"To know that 20,000 people annually lose their lives in India from snake-bites ought to be enough to arouse the indignant remonstrances of philanthropic folk; especially when we reflect that a twentieth part of that number slain in fair fight would be held sufficient cause for which to hurl an able and useful Government from power. But in all seriousness, if the death-rate in India is to be persistently reduced by the prevention of famines, the destruction of wild beasts, the killing of snakes, the prevention of internal wars and feuds, the punishment for murder, improved sanitation, vaccination, better medical treatment, public dispensaries, purified water, drainage and removal of malaria, and all the other resources of advanced civilisation—some frightful calamity will be brought upon the country by the awful increase in the population without any possible means of increasing the food supply. If these energetic interferences with nature's laws are to be extended, they must be accompanied by equally determined efforts to feed the additional millions preserved thereby; otherwise we shall be merely creating mischief with one hand, while combating it with the other. The prevention of the 20,000 annual deaths from snake-bites would increase the population of India by about ten millions every thirty or forty years, and it would be interesting to get the ex-Commissioner's opinion as to the means of feeding this vast increase. And we say this while deeply regretting the loss of life now going on, and recommending his book to the careful attention of all who profess an interest in their fellow-creatures." Flourish, then, malaria, snakes, and wild beasts, but save us from ourselves—from an increase of Indian population!

Correspondence.

CHEAP DISPENSARIES.—No. III.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is indignantly asked why, if such an innovation is necessary in medicine, it has not been found so in law? The reasons are not far to seek.

Law is not a necessity to the poor in the sense that medicine is; disease is no respecter of persons, it attacks those who are exposed to it, and therefore, the poor more than the rich.

Law is practically monopolised by two classes—the possessors of property and the perpetrators of crime. The poor do not belong to the first, and need not join the second; and consequently there has been no inducement to make law the handle of a vast pauperising machine under the misleading name of charity.

But not only is the need of medical relief infinitely more urgent and more general than the demand for law; but in most cases all that is really necessary to meet it can be accomplished with an expenditure of skilled labour, which is insignificant in comparison with the amount of time and trouble required to master the details of even the most simple legal case. What sort of legal cases are those which, for their urgency, frequent occurrence, and yet the small amount of trouble required to deal with them, can be compared with such ailments, for example, as an inflamed eye, or a splinter under the nail, an attack of sciatica, or an acute diarrhœa? In the majority of such cases, with the requisite knowledge, a few minutes' attention, a few plain directions, or some simple medicines are all that separate the sufferer from comfort, and when one remembers how easily and cheaply, comparatively speaking, such knowledge can be acquired, and with the adoption of some system how many such cases could be relieved in a day; and even with a very small fee in each case how fairly remunerative labour so expended might be; the indications of mutual help and advantage are as clear as any of those natural channels formed by the current of our social life; and what oracle or graven image, what shadowy interests or ancient prejudices have a right to warn a vast multitude of the people away from this highway unless they enter it as beggars?

It would be unsatisfactory to leave this subject without referring to the effort which is now being made on a large scale to carry out the principle of cheap fees by means of provident dispensaries, whose success I should cordially welcome. But it does seem to me that they have been scarcely fair to the principle which is their only hope of success, and have given far too much prominence to adventitious conditions which are not a necessary part of their system, and may prove rather a hindrance than a help to it, and have thus fostered widespread misconception, so that numbers of people who support provident dispensaries are ignorant that their sole *raison d'être* is that they supply cheap medicine.

Thus it is gravely asserted that real valid objections to small fees are completely satisfied if they are paid by the week on a provident principle. What a confusion of ideas! Teaching the poor providence is doubtless a worthy exercise, and as such should meet its reward; but it has no more special connection with medical fees than any other form of moral instruction; and if providence of this kind is such a blessing to those who practise it, why should all its benefits be absorbed by the poor and confined to medicine? Why should we not all forsake the long-trodden paths of wanton waste and vicious extravagance, embrace virtue, and pay for everything by the week?

Others, again, consider that practices, otherwise objectionable, are condoned if carried on under the supervision of a committee.

I am not prepared to deny that any institution might be better managed by a committee than an individual, but I have been hitherto arguing against those who denounce the whole principle of cheap fees, and if that principle is wrong, it cannot be made right by being sanctioned by a committee; and if it is right it is so with a committee or without. Quite distinct from this, but pertaining to the application of the principle, is the question of the influence a committee might possess for preventing abuses of any kind, and their value in this direction I should willingly admit, though the abuses which are apprehended seem to have been a good deal exaggerated.

One of the functions which it is often urged a committee would exercise as no individual could, is the prosecution of inquiries into the means of all patients attending cheap dispensaries, so as to prevent any who could afford a larger fee from taking advantage of them. But people often practise economies from other motives than necessity in many of their wants and pleasures; and if they are guilty of reprehensible meanness it would still be a rather drastic measure to put them on the level of ticket-of-leave men. If, however, such treatment is to be approved on the ground that we should attack the beginning of evil, let us be consistent, let us have committees to investigate the social and pecuniary position of every one who sits in the pit of a theatre or travels third-class.

On general grounds, however, no one who has had any experience of the committees of medical institutions can doubt the beneficial influence their supervision would shed upon everything they undertook. Who has not learnt something—directly or indirectly—of their calm impartiality, their enlightened discretion, their penetrating wisdom, their infinite tact? That there may occasionally be exceptions is possible, but they are happily far too rare to detract from the advantage that must accrue from having all the dispensaries that are required managed by legions of distinct committees of every variety and kind—*quot homines tot sententiæ*—a felicitous conception, the development of which must in due season cover its promotors with honour, and the people with blessings. Nothing, however, is further from my intention than to disparage provident dispensaries, which are an earnest effort to meet a pressing want, viz., to bring medical relief within the means of a large portion of the community who have hitherto been driven either to accept it as a charity or to do without it. And they deserve all credit for recognising the fact that this can only be done by some system which allows of the doctor's time being paid for by a number of fees small enough to be within the reach of the class it is intended to reach. But I protest against the confusion of identifying this, which is the keystone of the whole movement, with the provident principle, which may or may not be adopted as a corollary to a system of which it is no essential part.

Whether the provident system of paying for medical requirements is the best time will show. But it is questionable whether under the proposed methods of organising provident dispensaries there is not a risk of embarrassing them with too cumbersome machinery, overweighting them with the ubiquitous policeman and charity commissioner. We have yet to learn what business these officials have upon the scene at all. If dispensaries aim at being anything but self-supporting charities in which the self-supporting element is a delusion, they have simply to go into the open market with the best article for the money and subject to competition, and if their system is faulty they will be superseded by private enterprise, which will know how to meet the public requirements better. The question will finally be decided, not by individuals, nor even by committees, but by economic laws.

It is ever the misfortune of those who are enslaved by narrow views and groundless prejudices to be plagued by phantoms which originate in their own defective vision. But angry denunciations of a movement which springs from social wants and flourishes only by fulfilling them, are not likely to obstruct its progress any more than the sand-hills of children obstruct the sea. Should you at any time have space to waste on a letter whose length I will not attempt to excuse, its bestowal will confer a great favour on

Your obedient servant,

A. B.

DENTAL EXPURGATION.

THE business of revising the Dental Register, which respectable dental surgeons have been looking forward to with hope, seems to have come to a deadlock. The Dental Committee of the General Medical Council had been asked to strike off the rolls a large number of persons who had obtained admission thereto as being in the practice of pharmacy, though they were not, in a legal sense at least, engaged in any such practice. The Dental Committee doubted its competency to act as it was asked, and referred the request to the full Council, but it found that body as uncertain as to its powers as the Committee itself. The Dental Association put forth the opinion of Mr. Fitzgerald that the Council had full power to delegate its authority for this purpose, while Mr. Bowen, Q.C., was of a contrary view.

In any case the decisions of the Committee must be referred to the Council at large before they can be acted upon, so that the ultimate erasure of mis-registered names must probably take another twelvemonth.

AN ERASURE FROM THE DENTAL REGISTER.

THE case of Mr. John Hamilton, of Tavistock Street,

Bedford Square, London, whose diploma of Licentiate in Dental Surgery was last year cancelled by the Royal College of Surgeons in Ireland, because of his having published and advertised pamphlets of the usual semi-obscene character, was before the General Medical Council last week, and, on hearing the case, it was resolved that the qualification of L.D., R.C.S.I., appended to his name in the Dental Register, be struck out. The Dental Committee has still to consider whether the circumstances are such as to justify the removal of Mr. Hamilton's name from the list of registered dental practitioners. Under the 13th section of the Dentists' Act, the Medical Council is ordered to erase the name of any person who has been adjudged guilty of any "infamous or disgraceful conduct in a professional respect;" and it remains to be seen whether the Council may not consider the distribution of prurient quack books to be quite within the limits of professional propriety.

A MEDICAL TEST FAST.

A SHORT time since Dr. Tanner, of New York, determined in his own person to test the question of prolonged fasts, by submitting to a forty days' cessation from work and from eating and drinking (water alone excepted). Monday was the twenty-first day of his self-imposed fast, when, a telegram states, his pulse was at 78, temperature 98, and his weight 135 pounds. He sleeps soundly, drinks water quite freely, talks cheerfully, and looks fairly well. Up to the present time he has lost on an average about seven pounds in weight per week.

THE INTERNATIONAL MEDICAL CONGRESS OF 1881.

A MEETING of the Committee of Organisation was held at the Royal College of Physicians of London last week, when the date of the Congress was definitely settled, viz., from August 3 to 9 inclusive. The meetings will be held in the rooms of the University of London. The following are the sections and office-bearers therein :—

President of the Congress.—Sir James Paget, Bart., LL.D., D.C.L., F.R.S.

Vice-Presidents of the Congress.—The President of Royal College of Physicians, London; the Presidents of the Royal Colleges of Surgeons of England, Ireland, and Edinburgh: President of the Royal College of Physicians of Edinburgh, and of the King and Queen's College of Physicians, and Faculty of Physicians and Surgeons, Glasgow; Master of the Society of Apothecaries, London, Governor of Apothecaries' Hall, Ireland; Professor Acland, F.R.S.; Sir George Burrows, Bart.; W. G. Busk. F.R.S.; Dr. W. B. Carpenter; Sir Robert Christison, Bart.; Mr. Luther Holden, F.R.C.S.; Sir J. Hooker; Dr. Hudson; Professor Huxley; Sir W. Jenner, Bart.; Mr. Thomas Keith, F.R.S. Ed.; Professor Lister; Dr. Robert MacDonnell; Professor Owen; Professor George Paget; Professor Burdon Sanderson; Professor Spence; Professor Allen Thomson; Sir Thomas Watson, Bart.; Mr. Spencer Wells, F.R.C.S.

Section I., ANATOMY.—*President*, Prof. Flower, F.R.S. *Vice-Presidents*, Prof. Macalister, M.D., Dublin; Prof. Rolleston, M.D., F.R.S., Oxford; Prof. Turner, F.R.S., Edinburgh. *Secretary*, Prof. Thane.

Section II., PHYSIOLOGY.—*President*, Prof. Michael Foster, F.R.S., Cambridge. *Vice-Presidents*, Dr. F. W. Pavy, F.R.S.; Prof. John Mallet Purser, M.D., Dublin; Prof. William Rutherford, M.D., F.R.S., Edinburgh. *Secretaries*, Dr. C. S. Roy; Prof. Gerald Yeo.

Section III., PATHOLOGY AND MORBID ANATOMY.—*President*, Dr. Samuel Wilks, F.R.S. *Vice-Presidents*, Dr. John Syer Bristowe; Mr. Jonathan Hutchinson; Prof. Sanders, M.D., F.R.S.E., Edinburgh. *Secretaries*, Dr. J. F. Payne; Mr. Marcus Beck, F.R.C.S., M.S.

Section IV., MEDICINE.—*President*, Sir William Gull, Bart., M.D., F.R.S. *Vice-Presidents*, Prof. Gairdner, M.D., Glasgow; Dr. Quain, F.R.S.; Dr. William Roberts, M.D., F.R.S., Manchester. *Secretaries*, Dr. Duckworth; Dr. W. M. Ord.

Section V., SURGERY.—*President*, Mr. John Eric Erichsen, F.R.S. *Vice-Presidents*, Prof. E. H. Bennett, M.B., Dublin; Prof. Humphrey, M.D., F.R.S., Cambridge; Mr. W. S. Savory, F.R.S. *Secretaries*, Mr. H. Greenway Howse, F.R.C.S.; Mr. Thomas Smith, F.R.C.S.

Section VI., OBSTETRIC MEDICINE AND SURGERY.—*President*, Dr. M'Clintock, LL.D., Dublin. *Vice-Presidents*, Dr. Barnes; Dr. Matthews Duncan, LL.D., F.R.S.E.; Dr. Priestley. *Secretaries*, Dr. Galabin, Dr. John Williams.

Section VII., DISEASES OF CHILDREN.—*President*, Dr. West. *Vice-Presidents*, Dr. Gee; Mr. Timothy Holmes. *Secretaries*, Dr. Donkin; Mr. R. W. Parker, F.R.C.S.

Section VIII., MENTAL DISEASES.—*President*, Dr. Lockhart Robertson. *Vice-Presidents*, Dr. Crichton Browne, F.R.S.E.; Dr. Maudsley. *Secretaries*, Dr. Gasquet; Dr. Savage.

Section IX., OPHTHALMOLOGY.—*President*, Mr. Bowman, F.R.S. *Vice-Presidents*, Mr. Critchett, F.R.C.S.; Mr. Henry Power, F.R.C.S., M.B.; Dr. Argyle Robertson, F.R.S.E., Edinburgh. *Secretaries*, Dr. W. A. Brailey; Mr. E. Nettleship, F.R.C.S.

Section X., DISEASES OF THE EAR.—*President*, Mr. Dalby, F.R.C.S. *Vice-Presidents*, Dr. Cassells, Glasgow; Dr. Fitzgerald, Dublin. *Secretaries*, Dr. Urban Pritchard; Dr. Laidlaw Purves.

Section XI., DISEASES OF THE SKIN.—*President*, Prof. Erasmus Wilson, F.R.S. *Vice-Presidents*, Dr. Cheadle; Dr. R. Liveing. *Secretaries*, Dr. Cavafy; Dr. Thin.

Section XII., DISEASES OF THE TEETH.—*President*, Mr. Edwin Saunders. *Vice-Presidents*, Mr. John Tomes F.R.S.; Mr. Charles Spense Bate, F.R.S. *Secretary*, Mr. C. S. Tomes, F.R.S.

Section XIII., STATE MEDICINE.—*President*, Mr. John Simon, C.B., F.R.S. *Vice-Presidents*, Dr. George Buchanan; Professor de Chaumont, F.R.S.; Dr. Douglas Maclagan, F.R.S.E., Edinburgh; Mr. J. Netten Radcliffe, F.R.C.S. *Secretaries*, Prof. Corfield, M.D.; Dr. Thorne Thorne.

Section XIV., MILITARY SURGERY AND MEDICINE.—*President*, Surgeon-General Prof. Longmore, C.B. *Vice-Presidents*, Sir William Muir, M.D., K.C.B., Director-General Army Med. Dep.; Sir Joseph Fayrer, M.D., K.C.S.I., F.R.S., India Office; Dr. J. W. Reid, Director-General Med. Dep. of Navy. *Secretaries*, Surgeon A. B. R. Myers, Coldstream Guards; Surgeon-Major Sandford Moore, Aldershot.

Section XV., MATERIA MEDICA AND PHARMACOLOGY.—*President*, Prof. T. R. Fraser, M.D., F.R.S., Edinburgh. *Vice-Presidents*, Dr. Lauder Brunton, F.R.S.; Prof. Sydney Ringer. *Secretaries*, Dr. E. B. Baxter; Dr. F. T. Roberts.

MUSEUM OF SCIENTIFIC APPARATUS AND MATERIA MEDICA. — *Museum Committee*, Mr. Jonathan Hutchinson, F.R.C.S., *Chairman*; Mr. Waren Tay, Mr. C. Stewart, Dr. G. V. Poore, Dr. F. Macnamara, Mr. J. F. Goodhart.

Reception Committee, Mr. Prescott Hewett, F.R.S., *Chairman;* Sir Trevor Lawrence Bart., M.P., Sir Henry Thompson, Dr. Farquharson, M.P., Dr. Lyons, M.P., Mr. J. H. Puleston, M.P., F.R.C.S., Dr. A. Vintras, Dr. Lionel Beale, Dr. Andrew Clark, Dr. Philip Frank, Mr. J. Cooper Foster, F.R.C.S., Mr. Ernest Hart, F.R.C.S., Dr. George Johnston, Mr. John Marshall, F.R.S., Dr. W. O. Priestley, Dr. Owen Rees. *Secretaries*, Dr. Samuel West, Dr. Seymour Sharkey.

Executive Committee, Dr. Risdon Bennett, LL.D., F.R.S., Pres. Roy. Coll. Phys., London, *Chairman:* Sir W. Jenner, Bart., M.D., K.C.B., D.C.L., F.R.S.; Sir James Paget, Bart., LL.D., D.C.L., F.R.S.; Sir William Gull, M.D., F.R.S.; Mr. Luther Holden, F.R.C.S.; Prof. J. Lister, D.C.L., F.R.S.; Dr. H. A. Pitman; Mr. W. Bowman, F.R.S.; Dr. Sieveking; Dr. Herman Weber; Mr. Jonathan Hutchinson, F.R.C.S.; Dr. J. Matthews Duncan, LL.D., F.R.S.; Mr. Prescott Hewett, F.R.S.; Dr. Andrew Clark; Mr. A. O. Mackellar, F.R.C.S.; Dr. A. B. Shepherd; Dr. P. H. Pye-Smith; Mr. W. MacCormac, F.R.C.S.

Invitations to attend the meetings will be issued to all legally qualified medical practitioners in the United Kingdom, and will be sent to the different countries of Europe, to America, the Colonies, and India. Papers may be read

in English, French, or German, and will be published in the volume of Transactions in the language in which they are read.

It will be necessary for all who wish to make communications to the Congress to intimate their intentions to the secretary before the end of March, 1881.

All communications respecting the Congress should be addressed to Mr. W. MacCormac, F.R.C.S., Hon. Secretary-General, 13 Harley Street, London, W.

Medico-Parliamentary.

HOUSE OF COMMONS.—THURSDAY, JULY 15TH.

PAUPER LUNATICS FROM INDIA.

THE Marquess of HARTINGTON, in reply to Sir H. D. WOLFF, who asked whether pauper lunatics brought from India and left chargeable on the rates of Portsmouth ought not to receive partial support from the India Office, as was the case at the port of landing in Essex, said that, considering the great advantages Portsmouth derived from the Government establishments there, he thought it was only fair that the town should be liable to a considerable portion, at any rate, of this expense. The matter was, however, under consideration at this moment.

MONDAY—JULY 19TH.

FEVER AND OUT-DOOR RELIEF IN IRELAND.

IN reply to Mr. Sexton and Mr. Parnell,

Mr. FORSTER said—I have received further medical reports in reference to the outbreak of fever in Mayo, which are, on the whole, encouraging. I am pleased to find that the fever has not spread more than it has done, considering the condition of the population. The relief given to the people through the Relief Committees has been principally in the form of Indian meal, and the state in which the people now are is very much owing to the sameness of the food. I trust that in a week or two there may be a change of food, but this will depend upon circumstances.

VACCINATION ACTS AMENDMENT BILL.

Lord R. CHURCHILL.—In view of the advanced period of the Session, and taking into account the lamentable result of the Chester election petition (the Right Hon. Mr. Dodson, President of the Local Government Board, unseated on petition), I wish to ask whether it is the intention of the Government to persevere with the Vaccination Acts Amendment Bill.

Mr. GLADSTONE.—I am afraid I have not given that attention to the Vaccination Acts Amendment Bill which I ought to have done. In consequence of the question of the noble Lord I will take care to communicate with the gentleman who was responsible for the Bill.

London School of Medicine for Women.—The annual distribution of prizes to students of this school took place last week, the Dowager Lady Stanley of Alderley presiding. It was stated that during last year 19 students had entered the school, 13 of whom were for thefull curriculum and 6 for one or more subjects. At the present time there were 20 women on the medical register, of whom 13 had been, in part or altogether, educated at this school. Nine students had passed the first half or the "previous" examination in Ireland. At the University of London one of their students passed the matriculation examination in January, and four had passed the preliminary scientific examination for the Bachelor of Medicine degree. The following prizes and certificates of honour were presented :—Botany, Miss Jacobs ; practical chemistry, and second year's prize for anatomy and second prize for physiology, Miss Cock ; forensic medicine and midwifery, Miss Kenealy ; pathology, Miss Butler ; chemistry and first year's prize for anatomy, Miss Harris ; first prize (given by the lecturer) for physiology and practice of medicine, Miss Prideaux. The financial report showed that the fees from students (£1,199) fell considerably short of the expenses, which were £2,218 for the year.

NOTICES TO CORRESPONDENTS.

MEDICAL TEMPERANCE ASSOCIATION.—The next quarterly meeting of this Association will be held on Tuesday next, at 4 p.m., in the rooms of the Medical Society of London, when a paper will be read by Dr. C. R. Drysdale on "Acute and Chronic Alcoholic Poisoning." Medical men and students are invited to attend.

ARMY MEDICAL CANDIDATES.—The next examination for commissions in her Majesty's Army will be held at the University of London on August 9th and following days. Intending competitors should address the Director-General, Army Medical Department, at once.

NAVY MEDICAL CANDIDATES.—The next examination will be held in August. The necessary forms are obtainable on application. Candidates will have to attend at the department on Thursday, August 5th, for preliminary examination as to their fitness.

TRANSLATIONS.—The following accepted translations are hereby acknowledged, and will appear as space permits :—

"The Physiology of Sleep and Dreams," translated by Edwin Jackson, B.A. Lond.

"Deafness: its Degrees, Causes, and Treatment," translated by W. Douglas Hemming, F.R.C.S.Ed.

"The Cholera of Fowls," by Prof. Pasteur.

ORIGINAL COMMUNICATIONS.—Several of the following accepted communications are in type :—

"On Fevers in India," by Surgeon-General Gordon, C.B., M.D.

"Lectures on Genu Valgum," by Osman Vincent, F.R.C.S. (illustrated).

"The Medicine of the Ancients," by Bernard Kelly, M.D.

"A New Hip Splint," by E O. Day, M.R.C.S. (illustrated).

"The Indian Medical Service," by a Madras Army Surgeon.

"Five Hundred Cases of Perforation of the Membrana Tympani," by G. P. Field, M.R.C.S.

"Clinical Notes on Hydrophobia," by J. Carter Battersby, M.B.

"On Pyæmia and Blood Poisoning," by J. Duggan, L.K.Q.C.P.

CLINICAL RECORDS.—The following are in type :—

"Case of Popliteal Aneurism treated by Ligature of the Superficial Femoral Artery," by J. P. Haynes, F.R.C.S.

"Cases of Cerebral Syphilis," by C. R. Drysdale, M.D.

"Heart Affections simulating Dyspepsia," by J. W. Martin, M.D.

"On Puncture of the Bladder per Rectum for Retention of Urine," by J. Gillespie, L.R.C.S.

"Periostitis of Left Tibia," by A. T. Norton, F.R.C.S.

REVIEWS AND NOTICES OF BOOKS.—The following are in type :—"On Pharmacology and Therapeutics," by T. Lauder Brunton, M.D., F.R.S. "The Surgeon's Pocket Book," by Surgeon-Major Porter. "The Organic Constituents of Plants and Vegetables," by Dr. Wittstein. "The Practice of Commercial Organic Analyses," by A. H. Allen. "Memoires de Chirurgie," par le Dr. Nepven. "Rocky Mountain Health Resorts," by C. Denison, M.D. "The Diseases of Tropical Climates," by J. A. B. Horton, M.D. "The Elements of Indian Medical Hygiene," by J. Lucas, F.R.C.S. "Climate and Topography in their relation to Disease," by F. A. Macnamara, M.D. "Manual of Diseases of the Throat and Nose," by Morell Mackenzie, M.D. "On the Bile, Jaundice, and Bilious Diseases," by J. Wickham Legg, M.D. "Report of the Caterham Imbecile Asylum." "Report of the Derbyshire Lunatic Asylum." "Report of the South Yorkshire Lunatic Asylum." "Practical Hints on the Preservation of the Teeth," by N. Stevenson, M.R.C.S. "Practical Surgery," by Ewing Mears, M.D. "Surgical Emergencies," by W. Paul Swain, F.R.C.S. "Hand-book of Physical Diagnosis," by Dr. Gutman. "The Carmichael Prize Essay," by Dr. Laffan. "Ambulance Lectures," by L. A. Weatherley. "The Hypodermic Injection of Morphia," by H. H. Kane, M.D. "Indian Medical Notes," by Dr. Hogg.

VACANCIES.

Ballina Union Workhouse.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, July 24.

Bradford Infirmary.—Surgeon to visit patients at their homes. Salary, £100, with board and residence. Applications before July 27.

Bucks General Infirmary, Aylesbury.—Resident Surgeon. Salary commencing at £80, with board, &c. Applications to Mr. G. Fell, solicitor, Aylesbury, before Aug. 3.

Glenties Union, Carrick Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Medical Officer of Health. Election, Aug. 4.

Glenties Union, Dungloe Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Medical Officer of Health. Election, Aug. 4.

Gort Union, Ardrahan Dispensary.—Medical Officer Salary, £140, with fees, and £10 as Medical Officer of Health. Election, July 29.

Hertford General Infirmary.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Chairman before July 24.

Manchester.—Assistant Medical Officer to the Workhouse. Salary, £150, with furnished apartments. Applications, endorsed "Medical Appointment," to be sent to the Poor-law Officers before July 28.

North Staffordshire Infirmary.—House Physician. Salary commencing at £100, with board, &c. Applications to the Secretary, Hartshill, Staffs, before July 27

Portsmouth Lunatic Asylum.—Assistant Medical Officer. Salary, £120, with board, &c. Applications to Chairman of Committee before July 28.

Births.

ANDREWS.—July 15, at Everleigh, Green Hill, Hampstead, the wife of James Andrews, M.D., of a daughter.

FRANKLIN.—July 14 at Welford Road, Leicester, the wife of G. C. Franklin, F.R.C.S., of a son.

HOPWOOD.—July 14, at Exeter, the wife of Surgeon-Major Hopwood, of a daughter.

PEARSALL.—July 11, at 13 Upper Merrion Street, Dublin, the wife of W. Booth Pearsall, F.R.C.S.I., of a son.

Deaths.

GWYNN.—On July 11, at New Street, Wem, Salop (very suddenly), Samuel Betton Gwynn, F.R.C.S.E., aged 57.

SPENCER.—On July 2, at his residence, Preston, Lawrence Wilson Spencer, L.R.C.P., M.R.C.S.E.

The Medical Press & Circular.

Abstract of Two Lectures

ON THE

ETIOLOGY OF TRUE LEPROSY.

Delivered at the Royal College of Surgeons, June 23rd & 25th.

By Professor JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital.

Mr. President and Gentlemen,—I hope you will not consider the subject which I have chosen an inappropriate one. It is not new; the disease has been reported on by many observers in different parts of the world, and much has been said and written about it in this country. Dr. Liveing made it the subject of some very interesting lectures delivered before the College of Physicians two or three years ago. Nor have I anything particularly novel to bring under your notice. I have taken an interest in the question, what is really the cause of leprosy? for some years past, have studied it whenever an opportunity offered, and have arrived at certain conclusions which I am about to set before you. I have expressed these opinions on various occasions, and am bound to add that they have not as yet been generally accepted. But I have never had so favourable an opportunity as the present for setting out fully and in order the grounds upon which my conclusions are based, and am, therefore, glad to have the chance of justifying them before so distinguished an audience.

I shall in these lectures deal only with the etiology of the disease, and shall restrict myself as closely as possible to this, giving only, by way of introduction, a short statement of the generally accepted facts regarding the pathology, &c., of the disease which are to be found in the best works on the subject.

It is not necessary for me to define true leprosy, or to point out in detail the distinctions between it and elephantiasis. These are now well known, and it is difficult to understand how any confusion could have arisen on the subject. Elephantiasis arabum is altogether a local affection, not affecting the constitution, and has no sort of relationship with the disease the causes of which we are about to discuss.

The chief facts relating to true leprosy, which all authorities are agreed upon, are, that the disease is obviously constitutional, that it is insidious in its onset, that it may affect persons of either sex and of any age, that it affects all the tissues, and that it may be transmitted by inheritance; obviously, then, it depends on some general cause, but as to what this is, there is, as yet, no general agreement.

By most authors two forms of the disease are described—the anæsthetic and the tubercular. This division was originated by Dr. Robinson in a paper which he read some years ago before the Medico-Chirurgical Society, but the distinctions which he endeavoured to establish cannot be sustained. There is no real distinction between the two varieties; in some cases the tubercular element prevails, in others it is chiefly anæsthetic, but the differences are only of degree, not of kind. The former is characterised by the formation of large, soft, glossy masses of swollen skin, accompanied by more diffuse swelling of the subjacent tissues; in the latter dusky patches appear on the skin, only slightly raised at the margin, depressed, and white in the centre, and quite insensible. I have here drawings of one of my patients; he had tubercles on the face, and the dusky anæsthetic maculæ on the leg.

Next, a few words respecting the pathology of the disease. The first change appears to take place in the nervous system; not in the nerve centres, but in the cutaneous branches, and in those to the muscles. In the course of the lectures which I delivered last year in this place, I described in detail the changes which take place in the nerves in leprosy, and I need not repeat the description. Briefly, the change consists in a growth of albuminoid matter under the neurilemma, forming large fusiform enlargements; this presses on the nerve tubules. It affects not only the nerve trunk, but also the lactile corpuscles, and, indeed, probably begins in the peripheral parts. Occasionally the trunk of a nerve, as, for example, the ulnar, may be attacked first, and then all the parts served by that nerve will be affected; but more commonly

the disease begins in the skin, and spreads upwards. The formation of the albuminoid material is the characteristic feature of leprosy; it begins in the nerves and skin, but sometimes attacks other organs, as the eye, and wherever it appears secondary disorganisation follows sooner or later.

The disease begins insidiously; a dusky patch or a small tubercle appears on the skin, and is, at first, scarcely noticeable, but the disease progresses slowly year after year until the patient becomes hideously disfigured and broken in health. In the districts where the disease prevails it is always considered to be incurable, but as the cause has never been recognised it may never have been removed, and thus the incurability of the disease may be due to the persistence of the cause; there is, indeed, evidence to show that the disease may be cured if the patient be removed to a healthy district.

It is a very chronic disease: the tubercular form is less rapidly fatal than the anæsthetic. The total duration varies greatly; the patient may live seven, ten, or even twenty years after the first appearance of the spots.

Leprosy occurs in parts as distant and as different as regards climate as possible, yet it is the same everywhere. There are said to be over 100,000 lepers in India; they are found in Norway, in the West Indies, in South America, in the north of North America, in China and in Palestine, and a few places on the coast of the Mediterranean. The disease is precisely the same in Norway and in India, in Barbadoes and in China; there is no distinction to be found anywhere.

It is not contagious. The ancients thought that it was, but all modern authorities say it is not. Neither in India nor in Norway is it found that any of those who attend on the sick acquire the disease. In Norway no one believes it to be contagious. The ancient opinion that it was contagious was partly due to the hereditary nature of the disease, which was thus more common in certain households, and partly to the fact that as all were exposed to the cause the disease spread widely, but as the real cause was not known, this wide dissemination was ascribed to contagion. The Rev. Mr. Deeds, in an interesting account of a visit to the Faroe Islands, published in the 17th century, mentions cases in which one married person was affected and the other not, and of diseased parents having healthy children, &c. Later observers all agree as to the truth of these observations.

The disease is hereditary, but only to a limited degree. We must remember that in most cases the cause is constantly present, and that the disease is continually being originated by this persistence of the cause: it is, therefore, difficult to say whether a given case is actually hereditary or not. Gion mentions the case of a family in which the disease was hereditary; they removed to Paris, and the hereditary transmission ceased. It has been said that the disease is only hereditary to the third generation, but this is probably due to some fallacy.

Most accounts of leprosy have been greatly complicated by errors of diagnosis. In olden times these were very numerous. People in general were so frightened of the disease on account of its repulsive aspect, its incurability, &c., that patients suffering from all sorts of different cutaneous diseases were confined on suspicion. In the Bible it is evident that several different diseases are included under the term leprosy: some of these must have been acute diseases. This made it very difficult to ascertain the cause, since the different diseases included were due to various causes. This was the case in India until within the last few years: leucoderma, or "white leprosy," was especially liable to be confounded with the real disease; it is, however, not constitutional, and has no relationship to true leprosy; lupus, morphœa, and iodide of potassium eruption have also been mistaken for it. Portraits of cases of leprosy originating in England have been exhibited at some of the meetings of the British Medical Associatian, but none of these have been cases of true leprosy. If such a case can be found let the patient be produced before one of the medical societies, not a drawing; they are very chronic cases, so there could be no difficulty in doing this.

The disease prevails endemically in certain districts, and may attack immigrants into those districts. In Norway the doctors say there is no danger whatever to the tourist, and I have been told by Indian medical officers that they have never met with an instance of the disease originating in a European, but a few such cases do occur. In Norway I heard of one instance—that of an officer of the German army, who had lived for some time amongst the fishermen, and had adopted their habits. I have in all seen twenty cases in about twenty years of Europeans who have acquired severe forms of leprosy during a residence in the East or West Indies. In a few of these cases the patients were quite young One was a boy, aged 12; he had lived in Calcutta for eight years, but the disease did not appear until some time after his return to England. The first signs were some brown spots on the legs; next an ulnar nerve became paralysed, then patches appeared on the face, and the case developed into one of tubercular leprosy. I have met with four or five other cases of leprosy in the children of English parents. In one instance the child was born on board the ship in which his parents were going to India; he lived there six or seven years, then came home apparently healthy, but became leprous a few months afterwards. In all the cases the patient had lived for some time in a leprous district, but had not been subjected to any marked peculiarity of diet. One patient was a common soldier, others were officers; they had lived in a leprous district, but had lived well. Another was a merchant captain, who was accustomed to go backwards and forwards between this country and Barbadoes two or three times a year; he only remained there about six weeks on each occasion, and lived for the most part on board his ship.

But it must be remembered that it was once common all over England; it is impossible to say when it appeared, for it is mentioned in the oldest records which are extant. We know that the ancient Egyptians suffered from the disease, and it appeared among the Jews after their residence in Egypt. Later we know that it was common all over Europe and in this country. In the eighth century leprosy in husband or wife was held to be sufficient cause for a divorce. In the eleventh and twelfth centures leper houses were founded in England, and a little later in Scotland also, but the disease was not introduced at that time; it had originated in very remote times, but Christian feeling was then excited, and there was a general movement towards improving the position of these wretched creatures, who had previously been neglected, as well as shunned, by all. The hospitals were first disused in England, and then in Scotland. In the seventeenth century leprosy was unknown in England, but still prevailed in the northern islands. In England it was most common on the coast, and lingered longer amongst the fishing population of Cornwall than anywhere else. A patient was admitted into the Edinburgh Infirmary at the end of the last century from the Orkneys; he came of a leprous family. That was the last case in these islands. The disease used to be common in Spain. Leper houses were numerous in that country; now only a few cases are met with in some of the towns on the Mediterranean coast. The disease disappeared everywhere as the science of agriculture advanced, as corn crops began to be more generally raised, and the general mode of life amongst the people was improved.

I have now called attention to the principal facts relating to true leprosy. It is a disease which, after being endemic for ages, disappears before advancing civilisation; it is not contagious, it is hereditary. It is the same in all races and in all climates; it is incurable, except by removing the cause, but the cause has never been discovered. Removal from an infected district will in time effect a cure. There is a large immigration of Norwegians into the United States. When this first set in the American Government was much alarmed about

the introduction of leprosy, and submitted all immigrants to inspection. Some patients with the disease were sent back, but many were passed unobserved. After a time the Norwegian Government directed an inquiry with the view of ascertaining the condition of those who were known to have been diseased when they left their own country, and it was found that in most cases the disease had died out, and that the tendency to hereditary transmission had ceased. But so long as the patient remains in the infected district treatment appears to be unavailing. Thus in Madeira I am informed that no case of contagion has ever been known *and no case of cure.* I showed a patient last year who had been cured by long residence in England; her face was much disfigured, but the disease had ceased to be active. Another remarkable fact is that the period of latency is sometimes very long; the patient may not manifest any signs of the disease for two or three years after leaving the district in which he contracted it.

Next we have to deal with the possible causes; and first among these come *poverty and hardship.* In Norway leprosy is said to be a disease of poverty, and that the well-to-do escape. But this does not hold good in other countries; it may affect the rich. Several of my own patients have been people in very comfortable circumstances who have been subjected to no sort of privation. And then, as leprosy often occurs in people not subjected to poverty, so extreme poverty and hardship exist in places where no leprosy is found. It has been suggested that it may be due to *a specific animal poison.* But then it would be contagious and would not be so markedly endemic. Besides, how could the complete disappearance of the disease in some places and its persistence in others be accounted for? There is nothing in common between leprosy and either syphilis or scrofula. As to the latter, the conditions might appear favourable in some places, as in Norway, where the houses are small and close and the living scanty and coarse. But then leprosy is still more prevalent in Burmah, where the people are well fed and live much in the open air.

Then it has been thought to be due to *a telluric miasm.* Against this there is the fact that it does not affect the casual visitor, nor even immigrants, except in comparatively rare cases. Can it be due to anything in the air or in the water? The wide differences in the climate and soil of the affected countries negative this. It is met with in places where the water is good and where it is bad, where it is hard and where it is soft.

If there is nothing in the soil, the water, or the air to account for the disease, can it be due to anything connected with the food? Bad food has been asserted to be the cause; but it cannot be due to bad food in general, because many of the worst-fed communities are free from the disease, and, on the other hand, it exists amongst people who are well fed. The disease is, however, the same everywhere, and the strong probability is that the cause must be the same everywhere. We have excluded all general causes except food; it is not due simply to bad or unwholesome food. Can it be traced to the use of some special article of food? This question I will endeavour to answer in my next lecture.

(To be continued.)

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 17, Bombay 28, Madras 37; Paris 24; Geneva 21; Brussels 24; Amsterdam 25, Rotterdam 25, The Hague 19; Copenhagen 23; Stockholm 31; Christiania 20; St. Petersburgh 49; Berlin 51, Hamburg 22, Dresden 26, Munich 40; Vienna 26, Buda-Pesth 35; Rome 24, Venice 25; Alexandria 47; New York 33, Brooklyn 21, Philadelphia 25, and Baltimore 26 per 1,000 of the populations. Small-pox caused 37 more deaths in Paris, and diarrhœa 473 in Berlin.

Original Communications.

THE PHYSIOLOGIST IN THE HOUSEHOLD.

By J. MILNER FOTHERGILL, M.D.

Part I.—Adolescence—(*continued*).

(Continued from page 45.)

It is abundantly clear that growth and education clash—often materially. The increasing demands of education must tell in time upon the physique; but now that the steam-engine is made to do the hard work of civilised life, probably well-cultured brains are more valuable than stalwart figures and massive muscles. Macaulay, in his account of the battle of Neerwinden, speaks thus of Luxemburg, the commander of the French army, and William Prince of Orange, the commander of the Allied English and Dutch armies:—"At Landen two poor sickly beings, who in a rude state of society would have been regarded as too puny to bear any part in combats, were the souls of two great armies. In some heathen countries they would have been exposed while infants. In Christendom they would, six hundred years earlier, have been sent to some quiet cloister. But their lot had fallen in a time when men had discovered that the strength of the muscles is far inferior in value to the strength of the mind. It is probable that, among the hundred and twenty thousand soldiers who were marshalled round Neerwinden under all the standards of Western Europe, the two feeblest in body were the hump-backed dwarf who urged forward the fiery onset of France, and the asthmatic skeleton who covered the slow retreat of England." Still we must not move too far in our brain-worship—exercise and physical development are good for health; and health is as desirable for good brain work as it is for good body work. The increasing attention given to athletics at the present time, demonstrates that this fact is not forgotten by those who superintend educational establishments. Forcing schools, where boys are taught everything except the value of stalwart healthy manhood, may pay the proprietors, and in a certain sense the pupils too; but they possess inherent drawbacks of no slight importance. They contrast unfavourably in some respects with our famous old-fashioned schools of national repute, where athletics seem to be the most important matter; and where, in imitation of the Universities of Oxford and Cambridge, to be in the boat eight is a thing more to be coveted than to be in the first class.

The remarks made above apply with still more force to girls' schools, where physical education is at the lowest point. The truly melancholy spectacle of a procession of young girls, funereal in its gloom, is one of the saddest sights that can be seen. How infinitely better it would be for them if they were engaged in some romp, where there is freedom of movement, and where a ringing laugh is not forbidden. It is bad for girls morally—as well as physically—to have no muscular enjoyment on which to expend their spare energy. It will go off somehow, and proprietors of ladies' schools had better see that it does not go in a wrong direction. Muscular exercise is as essential to health of mind and body in girls as in boys. Decorum may be a very desirable thing; but everything must not be sacrificed to it. If there were more physical education in girls' schools there would probably be fewer French novels, and even worse. The outside of the platter may be scrupulously attended to and be brilliantly clean, but that is no warranty for the character of its contents. Athletic youth may not always be very strong intellectually, but they are comparatively free from bad practices; and the morals of "tom-boys" would probably compare favourably with those of the demurest boarding-school young ladies.

There are bad practices which are linked with precocity where this exists side by side with early and imperfect

maturity. And here we must distinguish betwixt the consequences of bad practices—and the conditions which lead to them. It is not the big well-grown lad who is so ready to ape the ways of grown men; it is the little weedy boy usually who furtively smokes his pipe in some out-of-the-way corner, in some solitary lane. It is part of his precocious development, this desire to smoke. In calculating the effects of tobacco smoking upon boys this element in the case must neither be forgotten nor under-estimated. Big lads usually do not suffer from smoking. I learned to smoke at school, and risked many a thrashing for a smoke behind a hedge, or in a corner of the playground; but I was over the average height of manhood before I was sick with my first pipe. The lads who smoke prematurely are just the lads who should not smoke; and the consequences which follow after smoking are not all to be laid at the door of tobacco: and would not be if the whole truth were known. My objection to tobacco smoking is not a moral one so much—that it is wrong; my ground is that it is foolish and stupid. To be sure, we know that smoking is undoubtedly bad for a little boy; but how far beyond that, it is bad morally in itself it is difficult to say. It is certainly bad in so far as everything is bad which entails concealment—no matter what. When, boys or girls would not like any practice to be known to others, then they may be sure that that practice is wrong. Where there is concealment there is something to be afraid of, or to be ashamed of; it is not human to conceal what will elicit approval. No lesson is morally so important, and which should be so studiously instilled into children, as this one about concealment. Where there is something to be concealed there is something that is wrong and bad—no matter what it is. Wherever there is concealment there follows moral deterioration and a loss of self-respect. No matter whether it is tobacco smoking or theft; where there is something entailing concealment there is either sin or vice. Few children take to drinking; they have little opportunity, and not enough of money ordinarily; but of the boys I knew at school those who would get into an out-of-the-way tavern on a holiday, or, indeed, when the occasion offered, they have done no good. They "turned out badly" in after life. Of course it is needless to say a word on the subject of drinking for adolescents; it is bad enough and injurious enough for adults; it is trebly destructive for the immature. Bad lads take to drinking; and drinking in its turn makes bad lads into worse men. It is not wicked to take a glass of beer at a cricket match, or even to supper ordinarily, but usually it is quite uncalled for, and does no good. When it is thought man-like to be drinking, it shows that the boy-drinker is a silly fellow—too thorough a fool even to suspect it himself. To drink and smoke is silly and foolish; and, further, it indicates a type of being of a very undesirable order. The boy who smokes or drinks should be closely looked after; in all probability he will be found a bad lot all round. Of course he may have been led into it by bad example; but that shows that he is weak in the head. Probably he did not possess enough of moral courage to stand, or rather to withstand, chaff successfully. To be laughed at into doing wrong is a sorry reason for it. Still there are weak natures who yield to laughter, and break down before derision. It is astonishing, too, to those not familiar with schools, how much harm a bad lot, boy or girl, can do in a school; especially with those who are younger than the vicious individual. Corruption spreads sadly too fast among full-grown persons, but among children and adolescents vice progresses apace. The evil consequences of precocity are, however, most vividly seen when those changes are instituted which convert the sexless child into the male or female. This birth of sex is called puberty. This change is brought about by certain physical modifications which are accompanied by correlative alterations which gradually become established in the mind. The toys of childhood are abandoned; the child is ashamed of those playthings which were but yesterday its pride. The mind of the child becomes usually full of sentiment; wild, irrational, and romantic ideas reign in its consciousness. Very often there is much moodiness, and melancholy even. In some cases children become fond of solitude, and distracted from their studies in a manner which gives great concern, and much troubled thought, to those who have charge of them. The mental changes are commonly a source of much internal disquietude to the children themselves, who are undergoing this change. But of course this is not all. At this period the feelings towards those of the opposite sex become profoundly altered. Up to this period boys and girls, as a rule, avoid each other; boys are shamefaced in the presence of girls; girls are afraid of the practical jokes, the persecutions which boys practise towards them; probably up to a certain time girls are genuinely afraid of boys. The old feelings and the new ideas may become intermingled and twisted together; forming a curious incongruous mixture. Passion now enters into the mind; and at this time the grave importance of inherited tendencies and of the previous training becomes manifested. Much that has hitherto been in abeyance now comes to the front; and the character becomes altered accordingly. In a healthy boy sentiment reigns supreme. He becomes attached to some girl or woman, often with intense force. Usually the object of his worship is considerably older than himself. She may be single or married; it matters little to him, his attachment is one which is absolutely pure; it is the highest aspect of love, and the type of what affection ought to be. This may last for years, and in after life he can look back upon this first love as the most exquisitely delightful, the purest, the noblest of all his love affairs or attachments. Long years afterwards he will look back with longing to his love for the woman who was then mistress, empress indeed, of his affections with unalloyed pleasure; there existed no gross taint in his love, he can ever look back to it with satisfaction and delight. Whatever a man may experience, whatever his subsequent relations to the sex, his first-love always shines with the brilliant white light of purity and honour; the coloured rays found in after attachments are absent there. But such is far from being the case with those who are less fortunate in their inherited qualities and their bringing up. The mental characteristics with the naturally vicious, or those who have been corrupted by wicked servants or bad example, are different from what has been sketched above. The mind then sucks in all that is undesirable. Lascivious thoughts are cherished and kept constantly in the mind; obscenity prevails; ribald conversation is linked with impure thought. Literature is sought for and craved after which is full of lewd thought and indecent suggestions. Unfortunately, there are beings, human in little else than form, who pander to these vicious cravings; and the florid filth which finds its way into youthful hands, is such as to make the angels weep, and to cause a Christian country to hang its head in shame. If the pubertal changes be delayed until a larger experience and more decided views and greater knowledge exist—that is until the character is more pronounced—then the perturbations so caused test the system less severely. When they come on while the child is yet but a child, and often a vicious child withal, then the disorder produced is very great. The limited experience of the unformed mind can make less resistance to licentious thought; which, if a few more instructive years have passed over the youthful head, could be more restrained and controlled. Precocity is very undesirable at this time, and the precocious child is very apt to become vicious; and in order to hide this to become untruthful. Dr. Maudsley has pointed out how disturbing is this change in such children: "Given an ill-constituted or imperfectly developed brain at the time when the sexual appetite makes its appearance, and what is the result? None other than that which happens with the lower animals." The outcome is the lowest form of affection—as simply lust. Of certain unhappy children belonging to families subject to disease of the nervous system, he says that even when very young they "lie or steal with an ingenuity that is incredible to those who have not experi-

ence of their moral perversion; and display sometimes a surprising precocity of sexual feelings and propensities." And Jean Paul Richter writes: "Children, like savages, have a propensity to lie," and the vicious child will lie with the greatest audacity, and with horrible persistency; when its evil practices are likely to be brought to light. Children never realise that their elders have passed through precisely the same experiences as they are undergoing. Though their elders may find it simply impossible to converse with children on these subjects—they are not in ignorance of what the child feels and thinks. The plan of education which will persist in being blind to, and oblivious of, the sexual development of the child, has been found distinctly wanting; it cannot build up the character on a sound foundation, when this great physical fact is designedly omitted from their scheme of education. It is very right and proper that certain books should be kept out of the way of children; but it is not well to go on under the delusive belief that because the sexual nature of adolescents is thrust out into utter darkness, that therefore it will not affect them. Children have their own inner thoughts and their own instinctive consideration of their subjective sensations. Is it well that the budding child shall be kept in utter ignorance of the consequences which may result from the development of the passions? That it shall have no instruction on what may lead to its total ruin—body and soul? It is not well, say those who have given attention to the subject; it is not fair; it is not just to a child to allow it to strive darkly with its own thoughts; to leave it to find some information about itself and its promptings, in the unspeakable literature which it somehow or other hears about, craves after; and too certainly becomes possessed of—despite the utmost watchfulness of parents and guardians. Better that the child be frankly told that it must reason upon and understand that it is now subject to impulses almost inevitable, to which hitherto it has been a stranger. This new life often comes with a suddenness which is very disturbing. At other times perturbations exist which long precede the birth of sex, —the foreshadowings of the coming change. Bad companionships and vicious thoughts exercise much influence in fostering this early development of the passions; and therefore parents and guardians are careful, and wisely careful, about the associates of their children. Children often wonder why they are forbidden to associate with certain persons; told not to do certain things. They cannot realise that these regulations are for their protection; the reason is not—maybe it cannot be, but anyhow it is not—given to them. The minds of children are not always so thoroughly pure as some would assume; and they have their own ways of thinking, and their own ideas.

(To be continued.)

ON PYÆMIA, OR NON-SPECIFIC BLOOD-POISONING.

By JOSEPH DUGGAN, L.K.Q.C.P.I.,
Ex-Senior Scholar Therapeutics and Pathology, Q.C.G.,
Turloughmore, co. Galway.

THERE cannot be found within the whole range of pathology a more important and interesting study for the physician and surgeon than the subject I am now about to dwell upon. If we look back even to the past three or four decades and compare medical science and pathological knowledge to what it is at the present day, we cannot but be struck by the vast increase in the means which now lie at our command for investigating into morbid entities and morbid causes, and promoting pathological inquiry; the rapid progress of physiology, histology, and chemistry are daily opening up the more minute composition, structure, and elaborate function of healthy tissues, and of the causes of morbid lesions, the metamorphosis of healthy into diseased structure, together with a more thorough knowledge of vital and chemical agencies; the beautiful applications of medical science to the discovery and diagnosis of some diseases that heretofore baffled the researches of our greatest intellects; whilst in preventive medicine and surgery we glory in the progressive strides of the wholesome doctrines of hygeia, the institution of the antiseptic school, though yet in its infancy, has done much, and we hope ere long to see it prove itself more fully to the doubtful.

From the foregoing observations which I have touched on in a prefatory manner, I am naturally led to make a few remarks on a subject of vital interest, and of much importance to physicians and surgeons, for it often unfortunately sets in and gives a fatal issue to a well-nigh cured affection or to a successful and promising operation; it is that affection generally known as pyæmia, or purulent blood-poisoning, but it has been shown by recent observers that the affection is not produced by pus mingling with the blood, nor does it cause inflammation of the veins; it is therefore a misnomer—the name ichorræmia, or what is better, septicæmia, is, I think, the most appropriate term for this affection; numerous microscopic examinations of pyæmic blood and pyæmic deposits failed to discover scarcely any pus. Before a purulent wound, sore, or ulcerating surface assumes the pyæmic phase, their entire morbid structure and composition are, I may say, completely changed. What was laudable pus bathing healthy granulations, may perhaps, after the lapse of a few hours, have its secreting surface and secretions wholly and chemically altered into a sort of ichorous sanies of unhealthy character and odour; in a wound the lips are opened, everted, and dry, the bottom of the wound, which was covered with healthy granulations and creamy pus, becomes an ashen-coloured slough, from which runs a thin acrid ichor of a very fœtid smell.

The patient's general appearance is very much changed to one of sickly yellow or earthy colour, combined with a depressed and anxious countenance, &c., frequent pulse, vomiting, and prolonged shiverings or rigors without feeling cold, alternated with copious perspirations, &c.; but the pathology of this blood-poisoning is so well known to every medical man it is needless for me to discourse on that wide and extremely interesting division of its history, yet there are a few points, *sub judice*, not yet fully decided which are open to discussion. How is it the system gets diseased or poisoned in this affection? And how and by what means is it developed?

At one time it was the generally received opinion that the pus was absorbed and carried by the veins from the primary purulent centre into the general system, to be deposited here and there, according to some unascertainable elective affinity. Arnott stated it was due to inflammation extendiug along the internal surface of the veins, the formation of pus in their cavities, and from thence carried to the general circulation; but it was left to our great scientist Virchow to explain the real cause and nature of those pyæmic deposits; from his numerous and accurate experiments and scientific deductions (*a*) he tells us distinctly that the puriform fluid found in pyæmic deposits is not pus, but disintegrated clot.

And if there are diseased conditions of the veins besides, it is not the cause but the consequence of the clot within; thus he upset the old theory and that of Sedillot *in toto*, proving to a demonstration that those secondary diseased deposits originated from emboli, produced from disintegration of fibrine, and the crumbling away of the thrombi occupying the diseased veins of the primary centre of the disease, and also in certain cases the absorption of ichorous and septic fluids play an important *role* in the dissemination of this disease.

Dr. Bristowe, (*b*) in his admirable essay, sums up in believing that thrombosis alone is the more general explanation of the obstruction of the minute vessels which tend to secondary deposits.

(*a*) Virchow's "Cellular Pathology."
(*b*) *Vide* Bristowe On Pyæmia, Reynold's "Medicine," vol. i.

That great pathologist Virchow has, without cavil, unquestionably explained this morbid phenomenon satisfactorily, and may be regarded as the approved one of the present day. Yet I believe (with all possible respect and diffidence) there is a something that must precede, some other morbid course that acts prior to the disintegration of febrinous clot, an agent endowed with a kind of catalyctic force or power that causes this breaking up of fibrinous structures at the primary seat of purulent diseasead foci.

Our great poetical pathologist, the illustrious and immortal bard of Avon, truly describes this venomous touch, that

> "With a sudden vigour it doth curd and posset,
> Like eger-droppings into milk,
> The thin and wholesome blood."

Some time ago I was afforded an opportunity of obtaining some fluid taken from a diseased deposit in a pyæmic patient, and had it placed in the field of a microscope of rather high power. I observed in the fluid a number of ill-defined globules and granular matter, with myriads of bacteria and vibriones moving rapidly hither and thither. In order to further satisfy myself, I submitted more of the same fluid on the field of the microscope, and found the same appearance of the fluid as in the first observation; this led me to infer that those morbid organisms, or some fibrine ferment, were the principal agents in the breaking up of the healthy fibrinous deposits that ultimately formed those emboli, and hence those septic deposits that spread throughout the general system, their numbers increasing according to the amount of venous distribution, which are, on this account, more frequently found in the thoracic and abdominal viscera.

That this pyæmia or septicæmia can occur within the system, without external morbid causes, seems doubtful; it is a non-specific blood poison produced by infection, contagion, or some morbid agency, as septic organisms or fibrine ferment, acting on surfaces of broken continuity, such as wounds, sores, ulcerations, raw surfaces, fractures, &c., and also on the freshly evacuated uterus.

With reference to surgical and puerperal septicæmia, it cannot be denied that in ninety-nine cases out of a hundred the poison comes by infection or contagion. In the surgical wards of an hospital the traumatic atmosphere frequently induces this affection, and surely if erysipelas is in the same apartment the same holds good in the puerperal state; the parturient atmosphere particularly, if any way unhealthy or poisoned by the toxic germs from erysipelas, will very probably bring on this fatal affection. It is, therefore, absolutely necessary that all medical and surgical attendants, accoucheurs, dressers, nurses, attending such cases should have themselves well disinfected and absent themselves for a time from attending surgical and midwifery cases, &c.; the use of sponges, instruments, and appliances previously infected, should be most religiously cleaned and purified. As for sponges, and dressings, &c., they should be destroyed, and all the wards or apartments placed under the most exact disinfection and thorough cleansing.

Wounds brought in contact with those diseased germs floating in such a poisoned atmosphere, and suddenly changed from a healthy to an unhealthy appearance, the edges are everted and dry, the surface covered with an unhealthy ash-coloured slough mixed with a kind of purulent sanious coagulable lymph, and healthy fibrinous structures soften and break up; the nervous filaments in immediate proximity have their terminal branches bathed in this cachectic or ichorous fluid, and convey by their different branches those morbid impressions to the nervous centres, and hence we see the sudden change in the whole aspect of the patient, the severe and repeated shiverings alternated by copious perspirations; the earthy yellow appearance of the skin, which feels clammy, frequent diarrhœa, the hollow voice, with weak and frequent pulse, followed by nocturnal delirium, all these symptoms showing how powerfully the poison has acted on the nervous system assuming a sort of a dynamic fever, pleuritis, pericarditis or peritonitis; they ulimately set in with obstinate vomiting; the patient finally sinks.

The same morbid phenomena occur to those infected after child-birth, the natural secretions are arrested, the parts become hot and dry; secretions thin, scanty, ichorous, and of a fœtid scent; pulse frequent; abdomen tender and painful; with constant vomiting, and repeated attacks of shivering and sweating; one or more of the serous cavities are attacked, hence we invariably see peritonitis, or pleurisy, &c.; the countenance, sunken, anxious and desponding, is marked with a lurid redness of the malar eminences. All these symptoms, combined with ichorous secundines, forebode to the educated accoucheur the arrival of that most terrible and destroying malady, puerperal septicæmia.

Preventive medicine and hygiene have of late years done much towards arresting the spread of contagious and infectious diseases; stayed the havoc which they heretofore perpetrated on man and animals; diminished to a very great extent the mortality from those diseases, and spread those wholesome doctrines of cleanliness and sanitation as the cardinal means of preserving health and checking epidemics. Medical science and experience are showing daily to the general public the great benefit and absolute necessity for the adoption of this sanitary reform.

With reference to this blood poison now under consideration, cleanliness *par excellence* and thorough disinfection are very important remedies in arresting and controlling the spread of this poison, combined with the application and use of those antiseptic remedies and appliances its septic action on the system is neutralised or destroyed. As to the doctrines and researches of Pasteur, or of those who are opposed to him, I shall not here dilate, it would exceed the limits of my paper. The propagation of sporadic diseases is plainly due to vital organisms and their spores floating in the atmosphere; whether they are *sui generis* the essence of infection, or carriers of it, I know not, and can only answer, ignoramus.

When there is a dread of this infection it is scarcely necessary to observe the great necessity of perfect disinfection and the immediate use of antiseptic remedies in midwifery practice. This precaution is not adopted as frequently as it should be, or else we should not have such mortality after child-birth. Midwifery instruments, catheters, should be always washed and cleansed with carbolised solutions; and carbolised solutions of weak strength frequentiy injected into the vagina will be found to control septic action very much. Washing all utensils and napkins in like solution will also purify the lying-in chambers very much, and contribute to her comfort and safety.

The same preventive treatment is also applicable in wounds and surgical cases; besides a free and very diluted current of sulphurous acid gas should be constantly diffused through the wards. With reference to the antiseptic treatment of wounds, I deplore the diversity of opinion that exists, and the fallacious reasoning set forth against it. Some surgeons state that ordinary cleanliness and water dressing are just as successful as those who adopt the antiseptic treatment; but by far the probability of *immunity* is in favour of Listerism, it is there to prevent the occurrence of pyæmia or septicæmia, and also to keep wounds fresh, pure and untainted. Not so with the other system: it is devoid of protective power. The antiseptic treatment of wounds as adopted by Prof. Lister may be ranked as a great achievement in modern surgery, and an honour to the genius of her son, Lister.

In pyæmia or septicæmia very few remedial agents can be found of much benefit. The hyposulphides, indeed, are rational remedies; they were found most successful in the practice of Prof. Polli, of Milan, who first made

known their efficacy, and in every case I think their use would be beneficial.

In the treatment of specific blood-poisoning, such as small-pox, I used solutions of sulphurous acid in mixture with marked benefit; also permanganate of potash, chlorate of potash in bark, with like results; but none of those remedies succeeded so well in my hands as moderate doses of spirits of turpentine and liq. ferri perchlor. If those remedies are found useful in specific, they ought also to be of service in this affection, and I daresay the benzoate of soda would act beneficially, as I have used it in half-drachm doses very successfully in checking strumous purulent formations. The new remedy, calc. sulph., I have had no experience of, but I am strongly of opinion that it ought to be useful in pyæmic cases.

I may now state, in conclusion that these views which I have humbly put forth and discussed on pyæmia may receive slight or grave objections, but a fair and impartial criticism will take the plea, which is the design of the author, to eke out some better solution from more gifted and abler minds of the cause and spread of this blood-poison called pyæmia, and hence the discovery of its rational therapeutics.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY, F.R.C.S.I., M.B.

(*Continued from page* 28.)

Varicose Aneurism of Thigh—Ligature of Femoral—Injection of Saphena Vein. Occurred in a bootmaker, now 28 years of age, some fifteen years previously, by his involuntarily gripping between his thigh, to arrest its fall, one of the sharp-pointed knives used in his trade, the point of which transfixed the long saphena vein and penetrated the femoral artery. Since the accident, at irregular intervals, he had been frequently under the treatment of various surgeons. With the aid of occasional rest and the habitual use of an elastic bandage, he had managed to battle along, and of late years support a wife and family; but the increasingly-growing tumour and suffering coerced him to seek surgical treatment. Amputation high up having been elsewhere advised, he came to Mercer's for the purpose of having it done. A pulsating tumour, quite as big as a husked cocoa-nut, and largely prominent, occupied the anterior and inner region of the middle of the left thigh. In the upper and outer portion of the growth there was a considerable deposit of laminated fibrine, so much so that pressure on the artery above stopped pulsation, but was only followed by a reduction in size of the tumour to about half its bulk. At the lower part were two projecting nodules, hemispherical in shape, and about as big as walnuts; in these the heaving pulsation beneath felt painfully close to the finger, conveying the sensation as if but the thinnest of structures, liable at any moment to burst, intervened between it and the blood current. The long saphena vein dilated to the size of a man's thumb, traversed and was imbedded in the mass; there were enormously large knots of dilated and tortuous veins behind the knee and down the leg. The stethoscopic phenomena observable in such cases were well-marked. The thrill was loudly heard at the heart, and was distinctly audible to bystanders around the bed.

The day but one after admission the superficial femoral was cut down on; in doing so a large branch which ran across the troject of the wound traversely was unavoidably divided, and both ends required to be secured. The femoral, when exposed, was quite as big as a large man's middle finger, its coats thin and unhealthy-looking; the vessel was separated from its sheath for about an inch, and a double carbolised cat-cut ligature passed under, this was divided in the centre, one portion being tied about an inch below the origin of the profunda, the other portion at the lower part of the exposed artery, which was then cut between the two ligatures, and, as a matter of precaution, the divided ends of the vessel were further tied each by an additional ligature of the same material. A couple of points of interrupted suture were inserted, and lint, moist with carbolised oil, was placed over the wound. The limb was wrapped up in flannel bandages and surrounded by hot jars. Spite of these precautions, three hours after the operation the foot and leg had become very cold, and so continued till next morning, when warmth began to return. The tumour was quite solid. Three days after the operation a great deal of local inflammatory action (proving to be obstinate) occurred in the neighbourhood of the wound, which was slow to heal. (*a*) Save for some doubtful fluidity in the lower portion of it, the aneurismal tumour continued solid, and without pulsation or thrill, but this latter was soon detected again in the long saphena vein, which stood out large and distended, though mostly lessened in intensity to what it had been. For some weeks longer pressure of padded corks was kept up on this tube, and for a time seemed to promise good result, but the attempt thus to cause obliteration of the vein eventually proved ineffectual. Sixty-six days after the deligation an aqueous solution of perchloride of iron was injected into a carefully insulated portion of the long saphena vein, the region selected being the central two inches where it crossed the tumour; some local inflammation supervened, but no permanent benefit was obtained, and ten days later the proceeding was repeated, and also proved abortive. A week later the attempt was repeated in a patch of vein lower down, and now was followed by satisfactory local inflammatory action, which, in two days, had both spread up and down the vein, thoroughly coagulating its contents for its entire length. 101 days after the vessel was tied, but small progress had been made in the absorption of the tumour, to which systematic compression by an Esmarch bandage moderately tightly applied was now begun. Ten days later the man insisted on attending the funeral of one of his children, and went through a fatiguing day without any evil result: 148 days after the operation he left the hospital for good, his exit having been long delayed by recurrent attacks of more or less severe inflammation of the glands in the groin. The vein remained obliterated, and the aneurism was slowly getting smaller. Since his exit a favourable progress has continued to be reported, the man following his trade and supporting his family. (*b*)

(*a*) As has been repeatedly observed to be the case with operations for the deligation of arteries which have been long subject to instrumental pressure, in this case the wound continued daily to discharge a drop or two of healthy matter almost to the end of patient's stay in the hospital.

(*b*) The following addenda have been received as we go to press.—Ed. M. P. & C.

Subsequent Ligature of Common and Internal Iliacs.—On the evening of the 5th July [nine months after the deligation of the femoral], the patient came back to the hospital in consequence of there having been a slight bleeding from the cicatrix. He reported that since last leaving the institution there had been occasional attacks of inflammatory character in the region of the groin, and that one particular spot of the cicatrix, when healed for a few days, would give way and remain open for a time, discharging daily a minute quantity—a drop or so—of thin matter. On re-admission, the groin, together with the upper and outer part of thigh, and extending up to the ribs, was swollen, tender on pressure, with the surface covered by an erysipelatous blush. Pulsation existed in what may called the stump of the femoral, but the swollen condition of the surrounding parts made it impossible at this period to recognise with certainty how far any fresh aneurism formation might be present. Next morning a few drops of blood again came from the sinus. Though it could not yet be affirmed positively that such was the case, still fearing leaking from an aneurism, anxious consultation was held, and it was determined to watch further, meanwhile taking the necessary precautions to at once command the vessel should bleeding occur. As the inflammatory symptoms abated, palpation along the course of the external iliac showed that vessel to be much enlarged. On the night of the 8th it could be determined that an aneurism had formed on the stump of the femoral, and was rapidly increasing in size. At 7.45 a.m., the morning of the 9th, after a good night's rest, a terrible gush of arterial hæmorrhage occurred, though arrested "on the moment," it left the patient blanched and prostrate. In a couple of hours, when he had rallied a little, the external iliac was cut down on matted tissues, and enlarged adherent glands made the lower portion of the vessel unapproachable, but it could be felt to be enormously enlarged. The incision being prolonged in the direction of the tip of the last rib, the artery was followed up; it was tortuous and distended quite as big as a sausage, and in appearance strongly resembling a coil of intestine. The origin of the internal iliac, though atrophied rather than enlarged, not feeling quite healthy it was determined to tie it as well as the common iliac; both vessels were easily secured with carbolised cat-gut, and the wound closed by interrupted suture, with pro-

The Mineral Waters of Europe.

ANALYTICAL REPORTS ON THE PRINCIPAL MINERAL WATERS, FOR THE GUIDANCE OF THE PROFESSION AND THE PUBLIC.

By CHARLES C. R. TICHBORNE, LL.D., Ph.D., F.I.C.,
President of the Pharmaceutical Society of Ireland, &c.

WITH NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,
Lecturer on Materia Medica and Therapeutics at the London Hospital.

(*Continued from page* 48.)

In our previous article we spoke of the third class of waters, being the chalybeate or ferruginous. The iron in such waters is frequently the result, or at least is associated with the decomposition of organic matter; and this remark also applies to the next class, which are called sulphurous water (better sulphurated waters). It has been the custom in days gone by (the dark days of science) to value a water which smells like rotten eggs according to the vileness of that smell. Now, it is self-evident that although its odour may in a degree be a measure of the quantity or presence of sulphur, if that sulphur is produced from the reduction of mineralised sulphates by the decomposition of organic bodies, we must also take it as evidence of a very large proportion of matter in a most objectionable form. Sewage often smells strongly of sulphurated hydrogen, and we are bound to say, that unfortunately many of the so-called sulphur springs owe their sulphuretted hydrogen and alkaline sulphides to precisely the same cause. Such a water is simply poisonous, and the prolonged use of it must end in lamentable results. Fortunately Wanklyn's albuminoid ammonia process presents an easy and certain mode of determining this point. But the process when applied to sulphuretted waters requires a little modification. In an ordinary water it is usual to distil off the *free* ammonia from a given quantity of water, and to estimate this free ammonia by Nessler's test; the residual water is then distilled with an alkaline solution of permanganate of potassium which has previously been purified from ammonia. Any ammonia now found in this second distillate must proceed from the oxidisation of nitrogenous organic matter, the nitrogen in such a case coming off in the form of ammonia. But as the sulphuretted hydrogen would and does interfere with the reaction of the Nessler, we distil off in a flask the free ammonia, adding after the process has continued a short time, a few drops of a pure solution of peroxide of hydrogen. The free ammonia is thus lost, but is of no consequence to our experiment. In such waters free ammonia in reasonable quantities may be neglected.

Any remaining products of sulphur are oxidised by the second part of the process into the perfectly stable sulphuric acid which no longer interferes with the reaction of Nessler's reagent. We generally add a given quantity of the water under examination when deprived of its free ammonia, and sulphuretted hydrogen to the action of a considerable excess of caustic soda (from sodium) and permanganate of potassium for some time in the cold; and then distil and tritrate in the usual manner. Any ammonia now found in the distillate must proceed from nitrogenous organic matter present in the water, providing the chemicals employed are absolutely pure.

Sulphur, to be of any use therapeutically, or rather, we should say, to be of any use as a cutaneous stimulant, must exist as a sulphide, or as sulphuretted hydrogen gas.

The term usually applied to these waters is sulphurous. Now although used in medical and other works, and by the profession generally, it is evidently a term so misapplied that we shall confine ourselves in future to the term sulphurated. "Sulphurous" from every chemical analogy would convey the idea that the sulphur in these waters was present as sulphurous acid, or as the class of salts known as sulphites ($M''SO$)—whilst it really exists as sulphides (MS). These sulphides in the presence of water, or in their hydrated state give rise to the fœtid odour which is their chief characteristic. There are many modes in which we may suppose that these sulphides are produced geologically, for instance, the direct combination by igneous action of calcium rocks with sulphur, or sulphides, and the subsequent decomposition of the calcium sulphide by carbonate of sodium. Such a decomposition would be effected in the moist way if under pressure. The sulphur when in the assimilable form exists as sulphydrates of the alkalies and alkaline earths, which are easily decomposed, and give rise in such water to a fairly permanent smell of sulphuretted hydrogen—

$$\underset{\text{Sulphydrate of sodium.}}{2\,NaHS} = \underset{\text{Sulphide of sodium.}}{Na_2S} + \underset{\text{Sulphydric acid.}}{H_2S}$$

On boiling such a solution this decomposition is much more marked, and we ultimately get a perfect decomposition, so—

$$\underset{\text{Sulphide of sodium.}}{Na_2S} + \underset{\text{Water.}}{H_2O} = \underset{\text{Hydrate of soda.}}{2\,NaHO} + \underset{\text{Sulphuretted hydrogen.}}{H_2S}$$

The writer has in his previous researches proved that all salts in the mere act of solution are to a certain extent dissociated, and this fact is the cause of all soluble sulphides when in solution giving off sulphuretted hydrogen, or their acidulous radical. As this becomes oxidised into the higher or prolythionic acid—combines it with the base and fresh proportions of sulphuretted hydrogen are set free as long as any sulphides are present. It is generally stated that when the sulphydric acid is chiefly combined with calcium it gives a more permanent sulphuretted water, then when present as a sulphide of sodium; *cæteris paribus*, we doubt if this is strictly correct. The sulphydrate of calcium will give a more strongly smelling water by virtue of its more ready decomposibility.

We frequently find that sulphuretted waters of a true mineral origin have associated with their bases barium

---

vision for drainage from its dependant angle. At first the patient continued to rally, and reassured by the knowledge that the vessel was tied, expressed himself hopefully. Much pain on the front of the tibia was complained of. Seven hours later a change suddenly took place, the patient became rapidly pulseless, the respiration being slow and gasping. Death soon supervened. Under very unfavourable circumstances a local examination was effected, and the specimen secured. There had been no further bleeding, nor any special appearance to account for the last sudden change, doubtless wholly dependent on the morning bleeding. *The external iliac much exceeded the abdominal aorta in size;* it was a marvel how such a river of blood was controlled promptly enough to prevent immediate death. The obliterated saphena vein had atrophied and remained impervious. The specimen is being made the subject of careful dissection and preservation.

and calcium. This is the case in the Harrogate sulphuretted waters—one of the best waters of its class.

In fact it has been too much the fashion to run down the Home waters, and the Continental medical men are only too glad to make little of that which the professional men of this country seem to depreciate.

Special.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

At the Société de Chirurgie M. Deleus, one of the members, communicated a case of trepanation of the tibia he performed on a young man who, for five years, experienced great pain in the superior extremity of the right tibia. This portion of the bone was apparently thickened, and presented all the signs of ostitis, and there was every reason to suspect the existence of one of those encysted abscesses described by Cruveilhier. All medical treatment, particularly iodide of potassium in dram doses daily, having failed, trepanation was resorted to by M. Deleus, but no pus was found. On gouging through a part whose texture appeared to be softened and friable, the operator came on a cavity, but it contained no pus. The wound was closed up, and the man, who had suffered for five years to the point of losing all sleep, declared that his leg gave him no more trouble, the pain had completely disappeared. This fact seemed to prove, said M. Deleus, that there are other indications besides those of osseous abscesses for trepanations. M. Perier remarked that already three times he had trepanned the femur of a patient attacked with recurrent ostitis. After the first time the pain, which had been excruciating, ceased immediately. There was no suppuration, and the patient got well in three weeks. A few months afterwards the same patient returned complaining of the same pain, and desiring another operation. Her request was granted, and again the pain disappeared. Yet a third time she submitted to the operation, after which she got entirely well. In none of those operations was pus found. M. Després thought that if M. Perier had traversed the bone with a drainage-tube, to be left *in situ* for a year or two, his patient would not have had a relapse. M. Cruveilhier declared that he had practised trepanation five times, and twice only did he find pus. In one case he perforated the bone and placed a drainage-tube. M. Duplay had performed the operation for painful ostitis a dozen times, and always obtained good results.

A case of acute intoxication produced by iodide of potassium was recently observed at the Hospital Tenon. The dose administered was half a drachm, and to a man who had entered the hospital for a left hydrocele complicated with intense pain in the forearm and head. The symptoms observed were general malaise, fever, considerable redness and swelling of the eyelids, lips, and gums. The phenomena disappeared on the cessation of the potassium.

An Italian doctor communicated a case of "diffuse chronic bronchitis with abundant muco-purulent exudation," treated with acetate of lead, to the *Moniteur de la Policlinique*. The dose was two grains. The patient, who expectorated daily a quart and a-half, had the night following the administration of the drug but expectorated half-a-pint, and the cough, which before was very harassing, diminished. Each day the patient drogressed under this treatment, and at the end of a fortnight was completely recovered. It was not until the bronchitis had entirely disappeared that traces of the lead were detected in the urine. The conclusions derived from the above case are, that acetate of lead given from two to three grains in the twenty-four hours acts perfectly in muco-purulent bronchial catarrh, diminishing in a rapid and effectual manner the exudation, and with it the cough, and that its presence is not declared in the urine before it has already produced its salutary effects on the respiratory organs.

Dr. Planat, in *La France Médicale*, counsels the application of arnica in the treatment of furuncles purely inflammatory. Arnica arrests, with an extraordinary promptitude, these eruptions, probably on account of its action upon the vaso-constrictor nerves of the skin. The pomade Dr. Planet employs is composed of two drachms of the extract of the fresh flowers of arnica and half-an-ounce of honey. This mixture is spread on a piece of oil-silk and laid on the boil. The dressing is renewed every twenty-four hours. Two or three applications suffice to arrest the progress of the furuncle at no matter what stage of its development.

In fissures of the anus, instead of employing forced dilatation, which is the classic remedy, Dr. Hamon advises the following means, which has succeeded with him in fifteen cases consecutively: It consists simply in touching the fissure with a camel's-hair pencil imbibed in a mixture of chloroform 5 grammes, alcohol 10 gr. Two or three applications effectuated at two or three days' interval, suffier generally. The first time the pain is very acute, but diminishes on successive applications.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, JULY 28, 1880.

THE NURSING DIFFICULTY AT GUY'S HOSPITAL.

THE Committee appointed to inquire into the circumstances under which such extensive dissatisfaction has been created at Guy's Hospital has presented its Report to the Governors, by whom, moreover, it has been formally accepted. As might have been anticipated, and as we suggested would probably be the case, the action of the Committee virtually leaves affairs *in statu quo*, unless it may be said that a qualified approval of the innovating tendencies exhibited by the matron relieves the monotony by which the phases of the quarrel were being marked.

After fourteen days' labour the Committee have come to the conclusion that there has been nothing sufficient to justify the indignant opposition with which the medical staff of Guy's Hospital have resisted the efforts made to introduce unwelcome and unnecessarily hard-pressing, useless reforms in the nursing arrangements of the charity. The Report is singularly wanting in deference to the unanimous opinion of one important class of those interested in its verdict, namely, medical students. The whole body of these agreed in condemning the system under which the hospital has of late been nursed, and complained that the facilities for the study of disease now enjoyed by the students at Guy's are infinitely inferior to those that existed under the older *régime*. This was uttered, too, as no silent protest, but in a manner that plainly marked the depth of feeling that prompted its expression. Notwithstanding, the Committee of Investigation find that "there is no reason to think the present nursing arrangements give any real hindrance in the way of medical observation or practice on the part of the students." Against this must be placed the evidence of the students themselves, singly and collectively, not alone at Guy's Hospital, but wherever the system there in use is adopted; and this agrees in condemnation of regulations which, except in certain hours, force a student from the wards. This, however, is hardly a matter on which the Committee would be likely to pass a judgment possessing much value to the professional mind, seeing that it is a point on which lay and technical opinions are almost certain to vary.

The general tenour of the Report may be approved by the majority of readers, inasmuch as it sanctions the principle of non-interference with the directions of the medical staff. It is recommendatory, too, of a wider exercise of the virtues of patience by the matron, who is advised to wait the completion of all the changes she seeks to introduce, in the natural slow course of events, rather than hurry them on regardless of the traditions or wishes of the place she is reorganising. It is significantly explained that it would be unjust to demand the retirement of an official who was requested to *assume* the duties so energetically discharged up to the present by the matron of Guy's. It is shown that this lady was no voluntary seeker after the place; and further that her orders were issued under the belief that they needed only the treasurer's signature to give them all the authority of law. To this is attributed the violent disturbance subsequent to the first act of promulgation, but, oddly enough, the Committee have not seen that the fact of the course of action thus secured being persisted in for months after the amiable little mistake became known, renders it very doubtful whether a disposition so determined to disregard outspoken protest is one likely, on the suggestion of a powerless Committee, to change the tactics which have been guides for action during nine months. However it may be, we accept the teaching of the report, and are content to await the immediate outcome. No one can be alarmed by the praiseworthy attempt it makes to arrange an amicable settlement of the dispute. This has been the aim and desire of the whole medical profession ever since the unfortunate circumstances first became public. Whether or not medical men were aroused to feel an intense interest in it by the appearance in the April number of the *Nineteenth Century* of a foolish essay written by one "not now in the hospital," need scarcely have occupied the time of the Committee to inquire. They might better have directed their powers to demonstrating the falsity of the statements made in the paper, a proceeding to which they seem not to have thought themselves directed.

In the same way that the Committee ignore the outspoken objections of the students, so do they with the numerous and forcible demurrers raised from time to time by eminent members of the medical profession. In determining that "they could not find sufficient justification for the difficulties which had existed between the medical staff and the matron almost from the date of her entrance into the Hospital," they have elevated themselves as a judicial body high over the heads of gentlemen who are ordinarily assumed to be the *best* judges of what concerns the province in which their functions are exercised. For a lay committee to decide that medical men are without justification for their urgent dislike to arrangements, the disadvantage or danger of which only a trained mind can appreciate, is, to say the least, a proceeding of somewhat doubtful wisdom. It is desirable that this anxiously expected Report shall receive all the attention and consideration so weighty a document deserves, since it naturally disposes of every element of the controversy which has raged at Guy's Hospital; it may be looked on as a final instrument for the suppression of warfare, and the insuring of a lasting peace. That it will, in the hands of the governing body, be a weapon of much force may with propriety be doubted. For the two people chiefly concerned, the matron and treasurer, it will be a highly welcome proof that there are yet people eminent from their social position who are able to sympathise with and excuse the sentiments, by yielding to which too fervently at first, the much-abused innovations were hurried into being before the susceptibilities of the reigning staff had been trained to a nice understanding of their value.

To their haste it is the Committee attributes the whole trouble. It deals tenderly with the weakness, and seems to hint that the whole affair is but an illustration of the ancient adage *nemo omnibus horis sapit;* and would apparently put down to indiscretion the occurrences that have well-nigh been the ruin of a great institution.

We will, however, welcome any indications that the mild measures of retrogression hinted at, are to be adopted, and that by a gradual assimilation of the wishes of the nursing to those of the medical authorities, peace and harmony are about to be once again restored in the charity over the water.

DR. TANNER'S FAST.

America is a land of wonders in other than a sarcastic sense. It is, indeed, a land where many curious incidents have happened. For instance, when Alexis St. Martin shot away the anterior wall of his stomach, the accident permitted Dr. Beaumont to observe the progress of the digestive act in a manner that had never been permissible before; nor no one knows how long it may be before

a like accident may admit of similar observation. Nevertheless, when a man deliberately rejects the accepted theory that body-heat is produced like any other heat by combustion, or friction, and this latter may be put aside at once in this case, he stands in a very ticklish position as regards our opinion of his sanity, or of his acquaintance with chemistry. But when he offers his "vile body" for an experiment which involves the attempt to fast "forty days and nights," then the matter has a scientific aspect. As to the blasphemy involved in the experiment, that is no matter of ours. At first, Dr. Tanner's performance was regarded with such suspicion that the scientific portion of the profession in New York abstained from taking any part in the experiment. The members of the Neurological Society of New York offered to superintend the arrangements, but their terms, according to the *New York Medical Record*, were regarded as "too exacting." His so-called fast was watched, however, by what was there termed "eclectic" physicians, a superior form of irregular practitioner. That their "watch and ward" has been sufficiently rigorous for the matter to attract the attention of the profession proper, is a sufficient basis for our consideration of the subject. Dr. Tanner started off "square." For fourteen days he tasted nothing, so far as is known; not even a drop of water crossed his lips. On this regimen he lost fourteen pounds in weight. Then the symptoms, to say nothing of the subjective sensations, became such that he allowed himself a certain amount, over a pint, of water daily. On this he recovered four and a-half pounds in weight. At the time when he so far indulged as to take water his state was as follows: "His skin had a bluish tinge, his speech was incoherent, his manner flighty, and his temperature below the normal standard. These symptoms of brain-bloodlessness were relieved by drinking water, except a certain hesitancy in his speech, which some attribute to the difficulty of moving his pinched and drawn lips." Whether this last is the full explanation or not may be questioned. This water which he drinks is procured from a bubbling spring to which he drives daily. His indications after twenty-five days of his enforced fast were as follows: "Pulse 75; respirations 15; temperature in the mouth, 98·4°; weight, 132 lbs., being a loss of one pound and a-half in the last twenty-four hours." This diminution of weight, which was checked by the water-drinking, has returned. No doubt there was considerable exhalation of water from the body which entailed absorption of water from the tissues; and when water was once more taken in excess of the exhalation, it was absorbed by the tissues, and there was a certain restoration of weight. This has now again been lost, and further reduction of body weight has set in, this time with a steady increase. When after twenty-five days of abstinence from food he retired, it was observed that his manner was flurried and nervous, while he spoke coherently and without tremor. His articulation was distinct, and his eyes were bright, but slightly sunken. The elimination of phosphates is normal in quantity. There have been no stethoscopic examinations made of the state of the thoracic organs, but sphygmographic tracings indicate a decided decrease of decision in the heart's impulse; indeed it is no matter for suprise if the heart is beginning to feel as if a little more nourishment to it would be desirable. Its reserves of force must be pretty thoroughly exhausted, and syncope imperilling life must be impending. Hitherto Dr. Tanner had slept well, indeed heavily, as is the sleep of exhaustion; but at this date he was restless and disturbed in his slumbers. Further, when he was dressing in the morning he was attacked with cramp in his stomach, and complained of nausea and weakness. This is the first complaint of his stomach troubling him since he allowed himself water.

The experiment, then, up to this point is exceedingly interesting. The downward progress which compelled Dr. Tanner to take water on the fourteenth day was arrested thereby to a very great and instructive extent, but is now again inaugurated. In fact, there are indications of the brain giving way now showing themselves, and he acted the other day like a maniac in alarming a woman by putting his face to hers and making a grimace at her. The end of the experiment seems approaching, and the time drawing near when those around him must arrest his performance.

There are several points of interest to the professiou in this experiment, and the first is as to the genuineness of the test. Hitherto all like performances have ended in disaster when the watch was complete and unbroken. Already suspicion has been awakened, and a dispute arose as to whether or not something more than water was passed to him in a towel. The doctor seems to have been hurt in his feelings at this suspicion, which, however, has not been revived so far. Then there is the question of how far the facts, supposing them to be as reported, viz., that nothing has been taken but water, pure and simple, are compatible with our present physiological knowledge. Excepting those incidents which we regard as distinctly miraculous, certain things are so opposed to our general knowledge of facts; that is, they are beyond the pale of the credible.

There was the notorious Scarborough high temperature case, where the body temperature rose over 120° for some time. It is now almost beyond doubt that this temperature of the thermometer was due to friction; the girl rubbed the bulb in her night-dress until the heat was produced. So we must wait to learn what all the facts of this case are before pronouncing any positive opinion about it. All must admit that it is an experiment of the greatest interest to us. Hitherto we have regarded the body as possessing within itself about ten days' supplies, when all food was cut off. What can be done in the way of partial starvation is astonishing. Thus Seegen related a case where very little food was taken for several weeks, until 35 grammes of milk only were taken for a number of days. Here the insufficiency of food was accompanied by a distinct loss in body weight. Carpenter tells the story of a fat pig buried under a fallen chalk cliff which lived on its own fat for 160 days, and was reduced from 160 to 40 pounds in weight, but was alive when found. The crew of the *Arracan*, wrecked in the Indian Ocean, existed for seventeen days on a little water caught in a sail, the tissues of a bird, and the blood from a wound in a comrade's head. Yet they survived. This was obviously due to the high surrounding temperature. Had there been a low surrounding temperature the bodies of these men must have been burnt up to maintain the temperature

which alone is compatible with life. The story of the "Diana of Hull," a whaler which was caught in the ice in the autumn and escaped in the ensuing spring, when the crew were on a very spare dietary through six months of winter, tells what can be done on limited allowances of food even in extreme cold. The story is partially told in *Good Words* for this month ; and the fast of Dr. Tanner will cause medical men to read with intensified interest the account of that hungered crew.

Then there was the case of the imprisoned Welsh miners ; but they had water and a high surrounding temperature, entailing little occasion for the production of body-heat. According to the latest accounts, Dr. Tanner's condition was little altered, the daily loss in body-weight being about one pound. How long he may be enabled to hold out it is impossible to say in the face of what he has already accomplished.

THE SANITARY STATE OF DUBLIN.

Following close upon the Report of the Royal Commission, we have the replies of the medical officers of health of the North City Districts to the request of their dispensary committee for information as to the causes of the excessive death-rate of Dublin. The first of these reports is from Dr. Speedy, who assigns the excessive death-rate to the following causes:—"The ill-constructed and dilapidated condition of the tenement houses, overcrowding, and the defective drainage of the houses; the accumulation of filth in the middens and ash-pits in the City, many of which are in close proximity to the dwelling-houses, thereby causing the atmosphere to be contaminated with foul gases ; the damp and filthy state of the courts and lanes for the want of proper pavement and drainage ; want of extension of the main sewers, the present imperfect system of public scavengering—the neglected condition of the streets in the poorer localities is especially to be noticed ; the fœtid odour from the channel way in those quarters of the city is at times unbearable, caused in a great measure by the occupants of the tenements casting filth of all sorts into the streets ; in addition, vegetable matter and other objectionable stuff is deposited there by the small dealers.

" The existence of public manure depôts, where street refuse comprising every description of dirt is left, is prejudicial to the public health. The same objection holds good in the case of private manure yards, and also to the piles of manure permitted to remain in lanes and by-ways.

"Little or no facilities are given in Dublin to the working classes in the way of baths or wash-houses ; even in a number of tenement houses there is no water on the premises."

To this Dr. Speedy appends fifteen very valuable and practical suggestions, every one of which could be carried into effect by the Public Health Committee of the Dublin Corporation without the least difficulty, and without any material expense to the citizens if that Committee had any disposition or capacity for the work with which it is charged.

Again, Dr. Delahoyde says :—

" It is my firm conviction that to the filthy condition of most of the wretched tenement house in which the large portion of the labouring and artisan population reside, more than any other cause, may be attributed the state of endemic disease which has gained for our city such unenviable notoriety. These houses, built at a time when the science of sanitation was unknown, and now almost without exception in a ruinous condition, are the fruitful sources in its production and dissemination. In many of them no sanitary arrangements whatever exist, or where such are provided, they are generally of the most rude and imperfect kind. It is easy to comprehend that the basement and foundation walls become soaked in putrescent matter, the effluvia from which soon exhibit their effects in the pallid countenances and shrunken features of the occupier. The district of which I have immediate charge contains within its limited area most of the slaughter-houses and so-called market places on the north side of the City, and in alluding to the subject, I have no hesitation in expressing my belief that much of the unhealthiness at present existing in the City depends on the neglected and wretched condition of these places. The former are mostly situated in the thickly populated portions of the district, and are usually of such primitive and defective construction as to defy the best efforts of their owners to render them innocuous. In the latter, the almost entire absence of either construction or arrangement offers facilities for the disposal of unsound and unwholesome food, which must affect injuriously the health of those who partake of it ; whilst their filthy state, resulting from the want of efficient means to secure the removal and proper disposal of the refuse, which is consequently strewn about the adjoining streets, must necessarily render such places a source of danger which ought not to be overlooked.

"The large number of children who, owing to the carelessness and apathy of their parents, are unprotected by vaccination, is a source of the gravest danger to the community.

"The subject demands most serious attention, for in this district alone they reach a formidable number, and it would be well to discover whether existing means are sufficient to force compliance with the law, and compel people to regard their neighbours' safety by protecting their own offspring from the liability to contagion."

Dr. Ferguson's Report says :—

"The causes of the high death-rate appear to be of imperfect sewerage in the tenement houses, which houses formerly belonged to independent people, each householder then keeping the sewers from their houses, open and clean ; but now, every one or two rooms are tenanted in each house by a family, and the excreta from these rooms are thrown into the common sewer of the house, no one having any particular interest in keeping the sewer *clean and open* into the main street drain.

" I consider damp to be a frequent cause of disease, and many of those new houses in the district are inhabited before they are dry and proper sewerage made. Dung-heaps in lanes, particularly where families live in stables in proximity with them, and where the sleeping rooms are over the stables where the cattle are kept, *is also another cause of disease*, and in the old back-houses in White's Lane, the inhabitants of those dwellings live in close

proximity to the filthiest ashpits, which, in general, remain in a state of filth the whole year round."

Again, Dr. Strahan says :—

"On the unhealthy condition of the district the death-rate depends, and is owing to defective sewerage, defective privy accommodation in most of the houses, which are chiefly tenanted ones, originally intended for single families, but each room now is set apart for one or more families ; the landlords exacting as much rent as can be screwed out of the occupiers, and doing nothing to cleanse or purify the premises. The lanes and alleys, and generally speaking the thoroughfares, require more frequent scavenging, all sorts of refuse being in many instances allowed to accumulate for days."

Without going further into the matter, or occupying space with quotations from the other reports, we may say at once that there is a perfect unanimity of opinion that the excessive death-rate of Dublin is due almost wholly to the state of the tenement houses inhabited by the poor of the city. For that condition of things, of course, the landlords of these houses, who wring from the people the most scandalously exorbitant rents, yet refuse to expend any money in ministering to common decency, cleanliness, or salubrity, are directly responsible ; but the criminal negligence of these landlords and the abominable filthiness of the occupying tenants, the Public Health Committee of the Corporation, and no one else, is responsible. They have had since 1874 the fullest power and the greatest facilities for making Dublin healthy, and that without any material expense to the citizens ; and yet in the face of the clamorous remonstrances and earnest representations addressed to them, they refuse and omit to avail themselves of the authority given them by the Public Health (Ireland) Act. We repeat our former assertion, which any one who pleases can substantiate by reference to the sanitary provisions of that Act, that the Public Health Committee by a brief inspection of any house, and by a notice to its owner which would cost nothing, might if they pleased put that house in perfect tenantable condition within one month, and without the outlay of sixpence of public money upon it. If anyone doubts that the Committee possesses this power we are ready to give the exact words of the Act which confers it upon them.

Whether the Committee withholds its hand from this work because it is too indolent to undertake it, or, as has been hinted, because the owners of these filthy fever dens are men of wealth and influence, with many friends in the Corporation, we cannot say. But, in either case, it is the duty of the citizens to force the Committee to put its authority in action. We assert without hesitation that the pleas for doing nothing which that Commiteee has put forth are absolutely untrue, and that there exists no impediment to their remedying the disgraceful state of the tenement houses if they were pleased to do so.

THE INDIAN MEDICAL SERVICE.

In our present issue we publish some remarks on the Indian Medical Service from a junior officer's point of view. It so happens that a good deal of what our correspondent says on this subject has already been expressed in the pages of this journal, support being given to several points in which by the latest Warrant that service is placed at a material disadvantage as compared with the Army Medical Department. On the other hand, however, the Indian Service still possesses, at least in its civil branch, some important advantages over the latter, as, for example, its stationary appointments, including surgeoncies to political agencies, professorships in colleges, Presidency and district surgeoncies, and so on, none of which can be enjoyed by the purely military medical officer.

Our correspondent shows in a tabular form the number of administrative appointments in India under the regutions of 1867 and of 1880, there being a reduction of eight in the latter as compared with the former date ; thus the chances of promotion to which men naturally look as a reward for arduous duty in the subordinate ranks become diminished to a corresponding degree. The system of keeping medical officers on what is called "unemployed" pay while they are all the time themselves employed is manifestly unfair ; so, also, is the system of what is called "officiating" appointments, the rate of pay of which is less than that given to "permanent" incumbents. It seems to us that the whole system according to which pay is granted to medical officers as to others in India is capable of improvement ; as it is, *pay* is only one item of their income, *allowances* another, the latter granted according to different scales for particular kinds of duty. Rather we should say, have a definite rate of pay for each particular rank ; let it by all means be adequate, but let it be equal, for we cannot say of medical duties that one particular kind is of less importance than another ; nor can we avoid thinking that the system which prevails in India of paying public servants so much for this duty, so much for the other has many disadvantages in so far as the interests of the public are concerned, as it certainly has in regard to individuals. The Indian Medical Department is kept short-handed, according to our correspondent ; young surgeons are "knocked about" at great expense to themselves ; pensions are inadequate, and those who have entered since 1864 are deprived of the benefits accruing from the retiring funds, which then ceased to exist ; no body seeming to know why or wherefore, although, in their abolition, a most serious injury was inflicted upon the service at whose own expense they were maintained.

But there is one remark in our correspondent's letter that is not quite clear to us. It is this : "The present rates of pension will utterly preclude the idea of officers retiring who have not saved a considerable sum of money ; a difficult matter where the appointments are so indifferently paid, *and where there is so little money to be made in private practice.*" It seems to us that a service can scarcely be said to be under-handed so long as its members profess themselves like our correspondent as looking for private practice, doubtless to fill up profitably the intervals between his public duties ; also that it is hardly fair upon medical men not in the public service, but entirely depending upon their private practice for their livelihood, that *officers* in the public service enjoying the income and social status of their position should in a manner thus compete against them.

Notes on Current Topics.

Home *v.* Foreign Supply of Food.

THIS subject was discussed in a practical manner on Saturday, the 24th inst., at Mr. Collinson Hall's, Ditchley's South Weald, near Romford. Mr. Hall bears a name well known in agricultural circles. He farms an aggregate of 22,000 acres, and has at present 750 cows, all in milk for the London market; and his ambition is to make the number 1,000. Mr. Hall has his farm in the highest attainable condition, with steam cultivation carried out to the utmost extent. The problem of the conversion of starch into sugar, or an approach to it, before it is given to the cow, so as to be readily digestible, is worked out practically. Crushed oats and brewers' grains are put together to ferment for twenty-four hours, and given to the cows while sweet, before the mixture goes sour. Minute attention to all these details is essential to success, and Mr. Hall knows it. Foreign stuff for English cattle, Mr. Hall insisted, was necessary to produce milk profitably; and there stood a considerable grist mill to illustrate his belief. A special train from Liverpool Street, with carriages to meet it, conveyed over one hundred visitors round Mr. Hall's farms. A very handsome cold luncheon further prepared his guests for the consideration of the subject of profitable farming by modern lights. Mr. Mechi spoke among others, while Dr. Fothergill pointed out that the English farmer had now another competitor to meet, viz., the Western States milk farmers; and said that he had had several private consignments of cream from west the Mississippi, the last of which was all that could be desired, and this could be put on the English market at a very reasonable price. Among the company were Drs. Hardwick, Tripe, Dudfield, and others. The weather was most propitious, and the company heartily wished Mr. Hall all success in his spirited enterprise.

The Parkes Museum of Hygiene.

IT is now twelve months since this, the first permanent exhibition of materials, designs, and appliances for improving our means and methods of sanitation, was publicly opened in London, as a lasting memorial to that great practical hygienist, Dr. Parkes. The work then begun has opened up so wide a field, that the present *habitat* in University College is found to be too small for the rapid expansion continually going on; consequently, at the annual meeting in connection therewith, held at the Mansion House yesterday, under the presidency of the Lord Mayor, it was decided that as the museum had taken an important position as a centre of technical education, an appeal for funds should be made to the general public to enable the committee to establish it in a position more independent and more accessible than that which it at present occupies. In a building of its own, and in a central position, the utility of the museum would be largely increased, and the dissemination of a knowledge of the laws of health, so important to all classes and both sexes, would be very greatly facilitated. There is little doubt that this appeal, like the initiatory one, will be fully successful.

Sabbath-Day Recreations.

THE efforts of the Sunday League to secure the benefit of intellectual and physical recreation for the great masses of the people have been attended with a success which, though cheering in itself, needs yet to be very greatly multiplied ere the advantages to be gained are to be looked on as satisfactorily secured. The attempts of the Society styling itself the Sabbath-Day Observance Association have all along been directed to opposing the good effected by those who seek to drive the hard-worked labourer into the fresh fields and country air on the one day when he can possibly indulge in these luxuries, or in the intellectual recreation to be found in museums and picture galleries, lecture halls, and libraries. The Hon. Secretary of the National Sunday League is able to announce that in addition to the Grosvenor Gallery, the Annual Exhibition of British Artists, at Suffolk Street, Pall Mall, will be open to the public on Sunday next. Admission will be by ticket to be obtained on application, enclosing stamped addressed envelope to the Hon. Sec., 9 Conduit Street, W. It is satisfactory to find also that the Sunday excursions organised by the Society have been completely successful this season, as also have been the band performances in the park. It may with confidence be anticipated that ere long the reproach will no longer be applicable to England that it alone of European countries tolerates a "dull Sunday."

The Order of St. John.

DR. E. H. SIEVEKING delivered a lecture on the 19th instant, under the auspices of the Order of St. John of Jerusalem, "On the Employment of Discharged Hospital Patients." Few medical men have not, at one time or other, witnessed scenes of keen distress consequent on the inability of patients to settle to work immediately after leaving the ward in which they have undergone treatment during illness. The effects of this latter are often such as to render them thoroughly unfit to pursue their accustomed labour, and it becomes an important and pressing question how best to relieve them in their trouble. If the Charity Organisation Society performed its functions with efficiency, and were not too prone to strain at imaginary gnats, the office of assisting these unfortunate and thoroughly deserving cases might be left to it. Since, however, it is vain to expect any help from the quarter which might justly be looked to for it, it is perforce left to private munificence. The result of Dr. Sieveking's eloquent appeal has been to refer the whole subject for consideration by the Ambulance Department of the Order of St. John. This body may feel that it has with it the practical sympathy of the medical profession, and that all assistance possible to be rendered by hospitals without crippling their own resources will be readily forthcoming.

Dublin Hospital Sunday.

THE managing bodies of Dublin hospitals who desire that their institutions shall participate in this year's distribution of the fund have been informed that their applications must be sent to the honorary secretaries.

Vivisection.

THE attentive reader of ephemeral literature cannot fail to be struck by the rapidly increasing number of journalists who weekly inveigh against the horrors of vivisection. It may be that the anti-vivisection fanatics are blameable for the excitation of popular indignation against a practice of which those most ignorant of physiological investigations consider themselves well able to be judges. The utter nonsense which greets the eye almost daily, and even in papers well informed on most ordinary subjects, though it receives a merited contempt from the instructed reader, is yet calculated to tell disastrously againt the progress of research by stimulating a rabid opposition to scientific needs on the part of the multitude. As the supporters of the anti-vaccination movement have gathered strength from the unwise silence maintained by the profession in regard to truths whose incontestable nature they clearly apprehend, so it is with the vivisection question. In all controversy where fact and science are pitted against ignorance and assumption, the issue has never been nor will be in doubt. But the insidious influence of oft-repeated and uncontradicted assertions will do irreparable injury unless an effort ere long be made to stem the advancing tide of prejudice and ignorance.

The British Medical Association.

INVITATIONS to attend the Cambridge meeting of the Association have been accepted by Professors Brown-Séquard, Marey, and Ranvier, and Drs. Landolt, Lucas-Championnière, and Wecker, of Paris; Professor Busch, of Berlin; Professor Klebs, of Prague; Professor Donders, of Utrecht; Professor Gross, of Philadelphia; Professor Chauveau, of Lyons; and Dr. Toussaint, of Toulouse. At a congregation of the University of Cambridge on June 10, graces were passed by the Senate for conferring the honorary degree of Doctor of Law, on the occasion of the meeting of the British Medical Association, on the following gentlemen:—Dr. C. E. Brown-Séquard, F.R.S., Professor in the College of France, Paris; Dr. Chauveau, of Lyons; Dr. F. C. Donders, Professor of Physiology at Utrecht; Dr. S. D. Gross, of Philadelphia; Sir William Jenner, Bart., K.C.B., M.D., F.R.S.; Sir William Gull, Bart., M.D., F.R.S.; Sir George Burrows, Bart., M.D., F.R.S.; William Bowman, Esq., F.R.S.; the Rev. S. Haughton, M.D., F.R.S.; Joseph Lister, Esq., F.R.S.; Dr. Denis O'Connor, President of the British Medical Association; John Simon, Esq., C.B., F.R.S.; and Andrew Wood, M.D., F.R.S.E. Professor Paul Broca would have been similarly honoured; the intention, however, has been defeated by his death.

A Disgraceful Railway Station.

IT often occurs to us, and probably the same thought passes in the minds of most travellers by the South-Eastern Railway Company, What must foreigners think of the rotten cattle-sheds called London Bridge Station? To them it is the entrance portal to the metropolis, and as they look around at its felt-covered roof, its unpainted timber, and its whitewashed walls and ceilings, now turned black with age and dirt, well may they exclaim on reaching this gateway to the richest metropolis of the world, What a filthy place! And if, unfortunately, their affairs compell them to get out at the station, a second look would certainly confirm first impressions. They would find subterranean passages through which passengers pass almost as black as night, so that gas has to be burned the whole day long, waiting-rooms with huge holes in the ceilings and walls, where plaster will hang together no longer, and the South-Eastern Railway is so bent upon paying big dividends that it has no time or inclination to study the comfort or health of its patrons. Should the weather be stormy or the sun exceedingly hot, the narrow ledges which for years have done duty for a station will be found insufficien tto save them either from a drenching or sunstroke. Verily the whole concern reflects the highest discredit upon Sir Edward Watkin and the management in general. Now if the said foreigners will go a few feet farther, to the London Bridge Station of South Coast Railway, they will hardly find a greater contrast in the way of buildings in London. Here good management and a thoughtfulness for the well-being of others is everywhere observable. South-Eastern papers please copy.

Closing of a House for Recurrence of Fever in it.

DR. CAMERON, Superintendent Medical Officer of Health for Dublin, reported to the Public Health Committee on Friday last that he had compelled the owner of a tenemental dwelling to close it for the following reasons:—The house is a large one, and in each of the twelve apartments a family were lodged. Within a period of twelve months no fewer than eight cases of typhus fever had occurred amongst the inmates of the house, and one of the patients had died. Dr. Cameron found the house in excellent repair and clean, but he determined that it should be forthwith closed on the ground that it was saturated with the virus of typhus fever. It was therefore impossible that the virus of the disease could be extirpated by any process of purification and cleansing possible whilst the house was inhabited. Dr. Cameron stated that any such house, however well kept, could not be healthy whilst every room in it was day and night occupied by a whole family. He would, therefore, not consent to its being reopened until the landlord undertook to reduce the number of separate tenements from twelve to eight.

This is, we believe, the first instance of a tenemental house being closed on the ground of contagious disease having repeatedly recurred in it. We trust now that there is a precedent for such action that very many dwellings the abode of contagion will be closed up no matter what accommodation they may afford.

THE success of "Zoedone" has been so immense, that it had to be turned into a limited liability company with a capital of £100,000. The patentee, Mr. Johnson, receives £35,000 in fully paid-up shares as an equivalent for his services and patents. Probably no modern commercial enterprise has attained to such a gigantic success in so short a time.

Metropolitan Hospital Sunday Fund.

THE Council of the Hospital Sunday Fund met at the Mansion House on Monday last, under the presidency of the Right Hon. the Lord Mayor, to order the payment of the awards made to the several hospitals and dispensaries. The sum available for distribution exceeds by £4,168 that of last year, and is, after allowing a sufficient deduction to meet outstanding liabilities, £29,389 13s. 4d. This amount will be at once divided amongst the 130 institutions of the metropolis, in addition to which the Council are able to set aside £300 for the purchase of surgical appliances during the ensuing twelve months. The actual payments will be £26,646 13s. 4d. to eighty hospitals, inclusive of four institutions which may be classed as hospitals; and £2,443 to forty-six dispensaries. It is also proposed to make an award, as heretofore, to the Hospital of "St. John and St. Elizabeth," although its constitution differs somewhat from that of the general hospitals, but this is only a proper concession to the Roman Catholic clergy, who, as a body, most loyally and cordially support the Fund. It is gratifying to find that the Metropolitan Hospital Fund works year by year so well, and with so little friction to all parties concerned—so much so that in asking for further information from one dispensary and fourteen hospitals, deputations at once attended from nine, and gave the Committee of Distribution satisfactory explanations which secured the recommendation of higher awards than they otherwise would have had. The one dispensary was unable to justify itself, three of the hospitals made no reply, and the remainder expressed themselves satisfied to leave their cases in the hands of the Committee.

The several payments were ordered to be made, with the exception of the Eastbourne Convalescent Hospital, and this was ordered to stand over until some inquiry could be instituted into an alleged attempt at *proselytism*.

The pending dispute between the authorities of St. John's Hospital and their late physician, this, it was thought, should not be made the grounds of suspension on the present occasion. For the second time the Council has issued a valuable statistical analysis showing the number of beds in each hospital, and the number actually occupied; the number of in- and out-patients treated during the year, with the average approximate cost of treating them; the number of home visits from dispensaries; the cost of each midwifery case; the percentage of cost of management as compared with that of maintenance; the average amount of payments by patients; the average gross annual income and expenditure, and other items of information, which, being carefully compiled from returns furnished by the responsible executive officers of the several institutions, will be found well worth the attention of the managing committees, and, indeed, of all who take any interest in the economical and successful working of the several medical charities of the metropolis.

The Society for Relief of Widows and Orphans of Medical Men.

THE Directors of this Society held their usual quarterly court last week; the President, Sir George Burrows, Bart., in the chair. Fresh applications were made from one widow and three orphans and relief granted to them. The amount to be distributed for the half-year among the sixty widows and sixteen orphans now on the list of recipients was £1,317 10s. The expenses of the quarter amounted to £44 9s. Only one new member was elected. The Directors take this opportunity of announcing that under the new bye-law all registered practitioners living within a radius of twenty miles from Charing Cross are eligible for election as members of this Society.

Co-operative Stores as Pharmacists.

AFTER another long trial of patience the question raised by the Council of the Pharmaceutical Society in the prosecution of the London and Provincial Supply Association (Limited), for alleged infringement of the Pharmacy Act, 1868, came before the House of Lords last Tuesday week, and after the arguments of counsel on both sides had lasted during the greater part of that day and Thursday, the decision given has supported the previous judgment of the Lords Justices, against which the Pharmaceutical Society had appealed to the House of Lords.

This litigation is therefore now at an end, and the result is one leaving the Pharmaceutical Society powerless to prevent the continuance of limited liability companies to carry on the business of a chemist and druggist, so far at least as the Pharmacy Act, 1868, is concerned.

Inquest on a Doctor.—A Melancholy Case.

AN inquest was held last week by the Liverpool coroner on the body of Dr. George Davy Kerman, who was run over by a cab on Saturday night during the thunder storm. He was taken to the Bridewell and locked up under the supposition that he was drunk. Afterwards he was bailed out, and died at his father's house on Monday morning. A verdict of accidental death was returned.

Stimulation and Total Abstinence.

THE last annual report of St. George's Hospital, in an interesting table of the daily consumption of stimulants to which patients on their admission had been accustomed, adds that the largest consumer of spirits, æt. 30, took twenty to thirty glasses of gin daily; and that the largest consumer of beer, æt. 35, never exceeded twenty-pints a day. It is added, only one "total abstainer" can be discovered.

THE will of Dr. Alfred Swayne Taylor, F.R.S., the eminent toxicologist, has been proved under a personalty of £60,000.

ENTERIC FEVER is very prevalent at Natal, several officers and privates of Her Majesty's forces have succumbed to this zymotic during the last few days.

THE French Government has allotted to M. Pasteur the sum of 50,000 francs for the purpose of enabling him to carry out his researches on the contagious diseases of animals.

WE hear that the Treasury has sanctioned a grant of

£500 per annum to provide an additional number of Distinguished Service Rewards for the Army Medical Department.

Of the 192 candidates examined at the Royal College of Surgeons, England, during the past fortnight, 78 failed to satisfy the Board, and were referred for three months', and 12 candidates for six months' further anatomical and physiological study.

Fleet-Surgeon R. W. Beaumont is nominated to succeed to the medical charge of Haulbowline Hospital, *vice* Dr. Gordon, promoted to the rank of Deputy Inspector-General. The *United Service Gazette* remarks that "Fleet-Surgeon Beaumont is an officer of long and exemplary service."

In the principal large cities of the United Kingdom the rates of mortality per 1,000 last week were—Portsmouth 16, Leicester 16, Bristol 16, Edinburgh 17, Salford 17, Hull 17, Birmingham 17, Leeds 17, Bradford 17, Brighton 18, Glasgow 19, Wolverhampton 19, Sheffield 19, Newcastle-upon-Tyne 20, London 21, Manchester 21, Nottingham 23, Plymouth 23, Sunderland 24, Oldham 25, Liverpool 26, Norwich 27, Dublin 30.

The fund recently established by the Birmingham Philosophical Society for the endowment of original research, has now reached £820, by donations for investment, with an annual subscription list of about £80 a year. Among the donors is Mr. Darwin, F.R.S., who in a letter to Mr. Lawson Tait, F.R.C.S., writes, "I admire greatly the noble spirit of Birmingham in instituting this fund; I will give £25, and would give more, but, in truth, the claims on my purse are many."

The death-rate last week from the seven principal zymotic diseases per 1,000 in the large towns ranged from 0·7 and 1·7 in Plymouth and Bristol, to 6·3, 7·5, and 9·7 in Oldham, Dublin, and Norwich. Scarlet fever showed the largest proportional fatality in Norwich, Oldham, Bradford, Salford, and Sheffield; and measles in Sunderland. Small-pox caused 3 more deaths in London, 10 in Dublin, but not one in any of the other large towns. The deaths referred to diarrhœa, which had steadily increased in the four previous weeks, further rose to 258 last week, of which 165 occurred in London; they were equal to an annual rate of 2·3 per 1,000 in London, while the rate did not exceed 1·3 per 1,000 in the other towns.

At a meeting of the Metropolitan Asylums Board on Saturday, the clerk was instructed to call the attention of the Home Secretary to the serious inconvenience which has been experienced by the recent failure, without notice, of the supply of water to the Fever and Small-pox Hospital at Stockwell, and to transmit copies of the correspondence between the managers and the Southwark and Vauxhall Water Company on the subject; to represent to the Home Secretary the utter impossibility of carrying on with safety and efficiency the administration of an hospital without an adequate supply of water, and to express the hope that as this was the third time within three years that the managers have had to make a similar complaint the Home Office will take the matter into their consideration.

Correspondence.

THE INDIAN MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I shall feel obliged by your publishing the following remarks on the Indian Medical Department from a junior officer's point of view. The Government of India have proved by their recent orders that they do not consider the time for recruiting the Civil Branch of the Indian Medical Department in this country has yet arrived. I believe the time will soon come when Government will recognise the fact that it would be better for them to encourage locally trained men to take employment in India under the uncovenanted Civil Service rules instead of going to Europe to qualify, as they now do.

For many years to come the Government of India will require a considerable number of European officers; if so, I think it is an opportune time for ventilating the different points that are unfavourable to us in the present regulations, which, if continued are likely to render the service unpopular, and the officers discontented.

2. Government have reduced the number of deputy surgeon-generals in the Madras army by two, and have given no equivalent unless the rules regarding the sanitary commissionership counting as deputy surgeon-generalship be reckoned one. In a service like the Madras Medical Department, where there are very few well paid appointments, and where there is little money to be made in private practice, this is a great loss.

The Department generally has suffered very severely by the new changes, as will be seen by the following statement. True, the five sanitary commissioners of Bengal, N.W. Provinces, the Punjaub, Madras, and Bombay, have been allowed to count service as deputy surgeon-generals after they have attained twenty-six years' service, or from the date a junior has been promoted over them, but as these appointments already existed in the service, the concession does not make up for the loss of eight deputy surgeon-generals. Two of the sanitary commissionerships which have been abolished (in Burmah and in the Central Provinces) were held by officers of the Madras Medical Department.

3. We have been precluded from ever attaining the highest rank in the military department, and have been placed in a position in which we may have to serve under officers who have passed an inferior examination at the entrance competition, and who have not had the same opportunities for gaining experience in the tropics. Surely officers who have to organise and manage hospitals throughout India, and who have to treat the European officials of all ranks, gain experience enough to fit them for the post of surgeon-generals in the army, where they are already considered fit to be deputy surgeon-generals.

4. The rules which keep officers on unemployed rates of pay until they are posted to some appointment for which there is a sanctioned staff salary or consolidated rate of pay tell very hardly, especially on junior officers. Before entering the service they have been led to believe that while they are kept on the "unemployed pay" they will not be required to work except to pass the vernacular test. For some years the rule has been that officers have not been posted to permanent appointments until they have completed five, and even over five, years' service. Such officers may be posted to "officiating appointments," but in such cases they rarely draw the lowest rate of pay laid down in the memorandum regarding the position of medical officers appointed to H.M. Indian forces, in par. 10 of which 400 rupees a month is laid down as the minimum. This memorandum is given to each officer on application at the India Office. In several instances known to me officers who have not had permanent appointments have been detailed to do work for which there is no sanctioned staff salary, and have consequently been kept on these unemployed rates of pay. For example, officers in charge of the famine hospitals during the late famine, one of which hospitals was constructed for four hundred sick; again, all the junior officers sent on "field service," either attached as junior officers to regiments, or on general duty. In the last Madras Army List there were nine junior officers thus employed. In some

instances such officers are detailed for duty in the base hospitals, and sometimes had to take charge of sections of the different field hospitals. Medical officers sent into the districts on special civil duty are treated in the same way.

5. Officers of the A. M. D. joining now rank as captains, while officers of the I. M. D. still rank as lieutenants, and receive while at Netley a lower rate of pay.

6. A new rank of brigade-surgeon, combining special privileges, pay, and pension has been created in the A. M. D., and officers of the I. M. D. of equal or greater length of service serving with them will rank as their juniors.

Administrative Medical Appointments in the Indian Medical Department under the Old and New Rules.

	RANK.	Bengal.	Madras.	Bombay.	Total
Under the Rules published in 1864 and 1867.	Surgeon-General; pay, rupees 2,700 a month	1	...	...	1
	Surgeon-General; pay, rupees 2,500 a month	...	1	1	2
	Deputy Surgeon-Generals; pay, rupees 1,800 a month	13	6	4	23
	Total	14	7	5	26
Under the Rules published in 1880.	*Military.*				
	Deputy Surgeon-General; pay, rupees 1,800 a month	5	4	2	11
	Civil.				
	Surgeon-General; pay, rupees 2,700 a month	1	...	...	1
	Surgeon-General; pay, rupees 2,500 a month	...	1	1	2
	Deputy Surgeon-General, with local rank of Surgeon-General; pay, rupees 2,250 a month	2	...	...	2
	Do. do. pay, rupees 1,500 a month ...	1	...	...	1
	Deputy Surgeon-General; pay, rupees 1,800 a month	1	...	...	1
	Total	10	5	3	18

7. The examination for promotion has been done away with in the A. M. D., yet still is retained for officers of the I. M. D. where inferentially it is less necessary.

8. Furlough under the rules sanctioned by Government does not exist, and cannot as long as the department is kept underhanded. This has been the rule for many years, and medical officers nearly always find it impossible to obtain the authorised privilege leave, or any leave except on medical certificate.

9. The Department being kept so short-handed frequently necessitates the employment of junior officers soon after their arrival in the country in responsible positions as to the duties of which they have no experience. Another effect of the department being underhanded is that young medical officers are for some years knocked about from pillar to post, at great expense to themselves; this probably accounts in a great measure for the high rate of mortality and invaliding which has existed amongst the junior for some years.

10. The inadequacy of the rates of pension sanctioned has not been felt owing to the fact that the officers who entered the service before 1864 have their medical funds to keep them, a privilege which has been, unfortunately, denied to their juniors. The present rates of pension will utterly preclude the idea of officers retiring who have not saved a considerable sum of money—a difficult matter where the appointments are so indifferently paid, and where there is so little money to be made in private practice, as in the Madras branch of the I. M. D This must end disastrously for Government by keeping men in the service long after they should have retired. What is most needed is increased rates of pension all round instead of special prizes.

11. Some appointments lately made by the Government of India for which there were consolidated rates of pay sanctioned will only pay a junior officer to take up until he is promoted, or obtains something better. This is a departure from custom established in G. O. G. G., No. 370, of 1867, which made the rates of pay progressive, so that an officer would not be a loser on promotion, and that Government would not lose the advantage of the experience he had acquired.

12. In several instances officers of the Warrant grade have been posted to offices for which pay is sanctioned for a commissioned medical officer, notwithstanding the rules published by the Government of India in November, 1877. Again, it should be noted that one of the best paid appointments belonging to the Madras Department, viz., the post of senior medical officer at Port Blair, has been given to a Bengal medical officer, and several of the civil appointments in Burmah are filled by medical officers of the Bengal Department, although the custom was formerly to fill them from Madras, and the province is entirely garrisoned by Madras troops.

The civil medical administrative officer in the Central Provinces is in future to be appointed from the Bengal Medical Department, although a large proportion of the medical officers belong to the Madras Department. This appears scarcely equitable, and looks as if the influence of the Bengal Department preponderated with the Government of India *Mais les absens ont toujours tort.*

I have the honour to be, Sir,

Your obedient servant,

June 22nd. A SURGEON, Madras Army.

Literature.

DISEASES OF THE SKIN. (*a*)

THIS useful and interesting volume will require brief notice, as the work, from being published by the Sydenham Society, is in the hands of so many of the profession. It consists of three leading subdivisions—1st, ulcers, including those of syphilitic origin; 2nd, cutaneous neuroses; 3rd, parasitic diseases, under which are placed those affections in which vegetable parasites are observed, and all the animal parasites and the diseases caused by them.

The parts of the work which would probably be first consulted by a practitioner are the brief, often too brief, observations under the head, "Treatment." Taking up the remarks offered for our guidance in the section on "Pruritus," the successful removal of which is unfortunately often beyond our power, we may state that lately two highly interesting examples of pruritus vaginæ distinctly due to diabetes mellitus have fallen under our notice, and in these the administration of kreosote was of decided advantage, both in relieving the pruritus and improving the diabetic attacks.

In the pruritus of the aged we have found the local application of oil of staphysagria diluted with olive oil, and the internal employment at the same time of sarsaparilla in its old-fashioned form of sarsaparilla broth boiled with beef or chicken, of marked utility. In these cases also small doses of strychnia and tartrate of iron are usually of advantage. Another indispensable direction for successful treatment is the removal from immediate contact with the skin of all flannel garments, and, of course, as far as possible to insist on scrupulous cleanliness of the skin, a point of extreme difficulty to be accomplished with some elderly people fond of warmth and not over fond of soap and water.

In pruritus ani, of course the first indication always must be to correct as far as possible any hæmorrhoidal tendency and hepatic derangemement. For this purpose euonymin in two-grain doses with some aloetic aperient is of service, followed by a morning dose of some saline and alkaline aperient or a mineral saline water, but for local use the oleum juniperi with soft soap, &c., is very serviceable, and will often prove a reliable application.

Passing to the section on animal parasites we have petro-

(*a*) "Diseases of the Skin." By Hebra and Moriz Kaposi. New Sydenham Society. Fifth Volume.

leum oil diluted with olive oil and Peruvian balsam added, recommended as a successful mode of treatment for pediculi, which it undoubtedly is, but the far preferable application of oil of staphysagria mixed with oil of olives to dilute it is not sufficiently mentioned. Again, we have ample accounts of all miseries caused by the flea, with the happy news for intending emigrants that it is as yet unknown in New Holland (Australia). On this point we would gladly know something additional, and would feel greatly obliged if some of our Australian readers would state whether the good news is true, and, if so, where the fleas die on their journey outwards, and why. Let us add, that the great virtues of Pyrethrum-roseum powder, so well known to travellers in the East, and to many households at home for its valuable property of banishing these minor plagues of existence, is not mentioned. To all who desire a clean house free from their presence, its liberal sprinkling every few months on floors and beds will ensure exemption without emigrating to Australia from these irritating little creatures.

We consider this fifth volume of Hebra's classic work on affections of the skin is well worth ranking with the preceding volumes, and that taken collectively they form one of the best contributions made by the Council of the New Sydenham Society to our stores of English medical literature.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

PRESENTATION TO DR. BEATSON, OF GLASGOW.—In acknowledgment of his valuable services at the accident at Irvine on the 6th March last, Dr. Beatson, at a large company of the officers' mess at the Artillery meeting in Irvine, on Saturday, the 17th inst., was presented with a gold watch.

REGISTRAR-GENERAL'S RETURNS.—According to the weekly return of births, deaths, and marriages for the eight principal towns of Scotland, the death-rate for the week ending with Saturday the 17th July, 1880, was 18·6 per 1,000 of estimated population. This rate is 2·0 above that for the corresponding week of last year, but is 1·8 below that for the previous week of the present year. The lowest mortality was recorded in Greenock, viz., 12·5 per 1,000, and the highest in Leith, viz., 30·2 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·4 per 1,000, being 0·5 above the rate for last week. Acute diseases of the chest caused 58 deaths, or 32 less than the number recorded for the previous week.

SCARLET FEVER AND WHOOPING-COUGH.—The half-yearly meeting of the Scotch Meteorological Society took place in Edinburgh on the 21st inst., when Mr. Buchan read a paper on the relation of the weather to deaths from scarlet fever and whooping-cough, prepared by Dr. Arthur Mitchell and himself. All over Great Britain, he said, with few exceptions, scarlet fever reached its maximum in the end of the year. The exceptions were the towns between Manchester and Hull, across the country, the difference being greatest in the case of Hull, where the maximum of scarlet-fever was in February. In the English and Irish towns the maximum of whooping-cough was in the spring months, and in the Scotch towns in the early summer.

Medico-Parliamentary.

HOUSE OF COMMONS.—MONDAY, JULY 26TH.

CERTIFICATES OF PAUPER LUNATICS.

Mr. HIBBERT, in answer to Sir T. Lawrence, said the attention of the Local Government Board had been drawn to an article which appeared in a medical journal in October last, alleging that a species of black mail was levied in connection with the certificates of pauper lunatics in the Kensington Union, but that the officers of the Union denied that any such charge had been made. The report might have arisen owing to the great number of cases that had been sent to two particular officers of that Union, the reason why they were sent to them being that they resided in the immediate neighbourhood of the infirmary.

UNIVERSITY OF ST. ANDREW'S.

Sir. W. HARCOURT, in reply to Sir T. Lawrence, said the Government would consider during the recess the subject of the embarrassed financial position of the University of St. Andrew's, with a view to seeing, before next session, whether any steps could be taken to relieve the College from its pecuniary difficulties.

INTERFERENCE WITH THE DUTIES OF UNION MEDICAL OFFICERS.

Mr. W. WILLIAMS asked the Secretary of the Local Government Board whether it was competent to relieving officers of Poor-law Unions to disregard or overrule at their discretion the orders of the medical officers in reference to the supply of medical necessaries to the sick poor.

Mr. HIBBERT replied that, while the relieving officers had a certain discretion in such matters, they were cautioned by the Local Government Board to be very guarded in the exercise of that discretion.

Obituary.

DR. RANDAL Y. KENNY, OF KILLESHANDRA,

WE have heard with great regret of the death of an old and esteemed member of our profession, Dr. Randal Y. Kenny, which took place at Killeshandra, co. Cavan, on the 18th inst. Dr. Kenny was Medical Officer of the Killeshandra Dispensary District, and has been in practice for the last fifty years in that neighbourhood, where he held a high place in public estimation, not only as a skilful physician, but as a kindly, warm-hearted man, and an honourable and a high-minded gentleman. Dr. Kenny has been for some years past in failing health, and has consequently been assisted in his practice by his son, Dr. J. B. Kenny. His last illness, however, was comparatively sudden.

Medical News.

Royal College of Surgeons of England.—The following candidates having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 19th inst. :—

Ashdown, G. W. W., M.B. Ed.
Bentham, Newton, L.S.A.
Bendall, Howard, M.B. Ed.
Bott, Henry Septimus, L.S.A.
Brown, Charles
Chadwick, Wm. Fitton
Cohen, A. A., M.B. Aberd.
Colbourn, Thomas Walter
Hall, Thomas Lambert, L.S.A.
Johnston, Edward Cocks
Jones, G. Job, L.R.C.P.
Pickersgill, Edwin Pulleine
Routh, A. J. McConnel, L.S.A.
Spencer, Bertram, M.B.
Thomson, Arthur, M.B. Ed.

The following were admitted on the 20th inst. :—

Bredin, Richard
Carter, Godfrey
Dester, William Parker
Fraser, James William, M.B. Ed.
Godson, Edwin
Harris, David
Maguire, Robert
Marsh, T. A. Perry
Moore, Stephen H., L.R.C.P. Ed.
Morgan, C. Jeffrey, L.R.C.P. Ed.
Neatby, Edwin Awdas
Pope, W. Wippell, L.R.C.P. Ed.
Roocroft, William Mitchell
Searancke, Nicoll F.
Shettle, Harry W., L.R.C.P. Ed.
Thomas, David John
Twynam, George Edward
Wills, J. P. Budgett, M.B.
Wilson, John, L.R.C.P. Lond.
Winstanley, Robert Wyndham

The following were admitted on the 21st inst. :—

Barron, Alexander
Barrow, Roger William

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners held on Monday, the 5th July, and the following days, the undernamed gentlemen passed the several examinations for the first half of the Letters Testimonial, viz. :—

Howard William Achenson, Thomas Arthur Baldwin, Charles Dillon Barrett, Herbert Joseph Bermingham, John George Wright Bullock, Henry Bryant, Francis Philip Colgan, Robert Cochran, Patrick Joseph Dempsey, Charles Ernest Denning, Frederick William Exham, John Seymour Gelston, William Gardiner Jacob, William Walter Jones, Claud Henry McSwiney, Bernard Macguire, John Patrick Nicholls, Francis Randalf O'Brien, Edward Hyacinth

O'Dogherty, James O'Neill, William Kerr Shea, Vetury Alexander John Smith, James Cooper Lloyd Slawell, and James Alexander Swan.

NOTICES TO CORRESPONDENTS.

A STRING OF QUERIES.

X. N. asks:—1. Where can a private practitioner obtain pure vaccine-lymph? 2. Is it likely that a candidate could pass the final written and oral examination for the licence of the King and Queen's College of Physicians on his own reading? I would like very much to go up for it, but I have always heard it said that no one, no matter how well they were read, could pass the examination unless they were coached. I am too far away from a grinder, and could not spare the time to go to one. 3. Would the L. G. B. be likely to again sanction the appointment of a medical man whom they dismissed a number of years ago from a dispensary in a different district for drunkenness and laziness? 4. Has the Victoria University obtained any additional provision to its charter to enable it to grant medical and surgical degrees?

[1. From the vaccine department of the Local Government Board, Upper Sackville Street, Dublin, gratis. 2. A studious candidate may readily pass without "grinding," though to do so is a much more tedious process. The unground student has, however, the subsequent advantage of knowing more of his business if that be considered of any value to him. 3. No; the L. G. B. has allowed dismissed officers to act as temporary medical attendants of dispensaries, but, so far as we know, has not allowed them to be permanently appointed. If the officer resigns under pressure, he may hold office afterwards, but not if he be dismissed by sealed order. 4. No; the power of the Victoria University to grant medical degrees has been suspended by the Privy Council pending the settlement of the general question of medical reform.—Ed.]

Excelsior.—We understand our correspondent to advocate the co-operation of the Poor-law Medical Officers of Ireland with the Irish Medical Association. The organisation mentioned in the letter knows little, and does not care much for the grievances of Irish dispensary doctors.

Holloway.—*Dorvault's Officine* gives the composition of Holloway's pills thus:—144 pills contain aloes, 4 gr.; rhubarb, 1·7 gr.; pepper, 45 gr.; saffron and Glauber salts, 2 gr. of each.

Surgeon-Major Martin will please receive our best thanks.

Studens.—1. Bryant, Gant, or Holmes's Surgery. 2. Foster's Physiology, and Harris and Power's Physiological Laboratory. 3. Leishman's "Midwifery" and Atthill's "Diseases of Women."

SUGGESTIONS FOR A MEDICAL AND SURGICAL BED-DRESS.

To the Editor of the Medical Press and Circular.

Sir,—When writing some suggestions for "a medical and surgical bed-dress" (*Medical Press*, July 14, page 25), I was not aware that Dr. Thomas Joyce, of Cranbrook, had previously made a similar suggestion for "a new form of bed-gown for sickness" in the *Practitioner*.

So far as the principle of our two communications is concerned, the original idea was clearly due to Dr. Joyce, and I hasten to acknowledge this. Had I known of Dr. Joyce's communication in time I need hardly say I should have referred to it in my own "Suggestions."

I am, &c.,
H. Cripps Lawrence, L.R.C.P. Lond., &c.

49 Oxford Terrace, W.,
July 22, 1880.

Job Lot Drug Selling.—The following is from the *San Francisco News Letter*:—The retail drug business in San Francisco, in spite of all we have been saying and doing to improve it, is still in a very poor condition. A friendly druggist has sent us a price-list of articles as he is selling them in his store. We copy a few items which may be of interest to our readers:—"Three emetics, 11c.; two blue pills and a black draught, and a bottle of Lubin's Ylang Ylang, 27c.; a box of itch ointment, a porous plaster, and a green shade for sore eye, 26½c.; a bottle of hair-dye, a box of rat-poison, and a fine tooth-comb, 42c.; an infant's feeding-bottle, a large fly-blister, and a pint of "Mother-in-Law's Delight Bitters," 1 dol. 3c.; a little bottle with a baby in it, a pint of cod-liver oil, and a box of Higgenbotham's Antiphlogistic Skolatoxicum, 95c. Everything else in assorted lots at proportionate prices. With all orders amounting to 25 dols. a stomach-pump will be thrown in."

IMPROVED RAILWAY COMMUNICATION WITH HEALTH RESORTS.

The authorities of the Great Western Railway deserve commendation for the marked improvement made this summer in the train service between London and Malvern—one of the most beautiful and health-giving of our English watering places.

In addition to the ordinary service, there is now an accelerated train from London accomplishing the distance in three hours and twenty-five minutes, leaving Paddington at a quarter before five and arriving at Malvern at ten minutes past eight. It is to be hoped that visitors will be induced to avail themselves of this quicker transit to a place so charming and refreshing to jaded townsfolk.

The beautiful hills of Malvern lie in the heart of some of the most perfect and typical scenery in England. They are green to their summits, breezy, bright, and fragrant; and a stroll over them is in the highest degree health-giving and refreshing. To know the full charm of a drink of pure water, clear, cold, and brisk from the rock, the hill-climber should drink at St. Anne's Well on his or her—for the hills are equally accessible to ladies—way up or down the chief hill. There are excellent hotels at Malvern, notably the Imperial; and pretty lodgings are to be found by those who will make a stay of weeks. For *re-freshment* by English hill-and-woodland-scenery no place equals Malvern.

Dr. Mulholland, Belfast.—A correspondent forwards us a newspaper containing a police-court report, from which it appears that Dr. Mulholland admitted on examination that he was, and is, the owner of several brothels in Belfast, and our opinion is asked upon the matter. Our opinion is, emphatically, that Dr. Mulholland disgraces himself and his profession by encouraging so abominable a traffic, that no respectable house-owner would knowingly let a house for immoral purposes, and that there is no possible excuse for doing so. It was sworn in this case that Dr. Mulholland actually evicted a solvent tenant in order that he might let the premises to the more lucrative, but less decent, occupants. In the course of the case the following conversation occurred:—The prosecuting solicitor, Mr. M'Lean, said that he was anxious that these houses should not be let to other parties for immoral purposes, and he hoped his Worship would make an intimation to Dr. Mulholland to that effect.—Mr. Lloyd thought that Dr. Mulholland should be ashamed of himself for letting the houses for improper purposes; some person should be made amenable. He thought that person was Dr. Mulholland, and if there was a law by which he could be made amenable he would have that law put in force.—Mr. M'Erlean said that on looking into the law he found that a landlord who let his houses at an exorbitant rent to persons who kept houses of ill-fame could himself be punished.—The case was adjourned for ten days, the defendants to leave the town in the meantime.

HYPERIDRÓSIS.

To the Editor of the Medical Press and Circular.

Sir,—Would you or any of your numerous readers give me a hint as to the treatment of an aggravated case of hyperidrosis?

The sweating is almost completely confined to the hands. It is acid. Health good; all functions regular. Purely a nervous affection, but very unpleasant to the patient, and not very amenable to treatment. T. Fox, J. L. Milton, and others are silent as to the best means of cure.

Yours, &c.,
P. Q. R.

VACANCIES.

Buckinghamshire General Infirmary.—Resident Surgeon. Salary commencing at £80, with board. Applications to Mr. Fell, solicitor, Aylesbury, before August 3.

Swansea Hospital.—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary before August 4.

Warneford Hospital.—House Surgeon. Salary, £100, with board. Applications to the Secretary at Leamington before August 9.

Wigan Infirmary and Dispensary.—Junior House Surgeon. Salary, £80, with board. Immediate application to the Secretary.

APPOINTMENTS.

Constable, J., M.D., C.M., Medical Officer and Vaccinator for the Parish of Logie, Fifeshire.

Dunlop, J., M.B., C.M., Assistant Medical Officer to the Woodilee Asylum, Lenzie, near Glasgow.

Goude, H., F.R.C.S.Ed., M.R.C.S.E., Resident Surgeon to the Small-pox and Vaccination Hospital, Highgate Hill.

Haslett, J. C., M.D., M.Ch., Honorary Physician to the Ulster Hospital for Children, Belfast.

Horne, A. J., L.R.C.S.I., L.K.Q.C.P., Assistant Physician to the Rotunda Hospital, Dublin.

Jones, J. R., M.B., L.R.C.P.L., House Physician to the Hospital for Women, Soho Square, London.

Jones, R. R., M.R.C.S., House Surgeon to the Newcastle Infirmary.

Keelan, P., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Callon Dispensary, Ardee Union.

McArdle, J. S., Resident Surgeon to St. Vincent's Hospital.

McDonnell, E. P., L.R.C.S.I., Resident Surgeon to Jervis Street Hospital, Dublin.

O'Connor, C. J., L.R.C.S.I., L.K.Q.C.P., Medical Officer to the Clane Dispensary, Naas Union.

O'Dea, P. St. L., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Ennistymon Dispensary, Ennistymon Union.

Price, T., M.R.C.S.E., Medical Officer to the St. Michael District of the Manchester Union.

Spofforth, J., M.R.C.S.E., L.R.C.P., Honorary Surgeon to the Kidderminster Infirmary.

Walsh, J. L., L.R.C.S.I., L.R.C.P.Edin., Medical Officer to the Kilmacthomas Dispensary, Kilmacthomas Union.

Births.

Kennefick.—July 15, at Auburn, Clonmel, the wife of John S. Kennefick, L.R.C.S.I., of a daughter.

Phillips.—July 13, at New Ferry Park, Cheshire, the wife of E. J. M. Phillips, M.R.C.S., of a son.

Deaths.

Domville.—July 22, at Greenwich, Edward A. Domville, eighth son of Inspector-General Domville, M.D., aged 51.

Kenny.—July 18, at his residence, Killeshandra, co. Cavan, Randal Young Kenny, M.D., aged 76.

Morrison.—July 21, at 107 Lower Baggot Street, Dublin, John Morrison, M.D., F.R.C.S.I., aged 75.

Percy.—July 17, at 1 Gloucester Terrace, London, Grace Mary, for forty-one years the wife of Dr. Percy, F.R.S.

Thomas.—July 16, at Wells Street, London, W., W. Edward Stevenson Thomas, M.R.C.S.E., aged 47.

Ward.—On July 10, at 28 Finsbury Circus, London, Stephen Henry Ward, M.B., M.D., F.R.C.P., aged 61.

Wilkinson.—At Clonaslee, Queen's co., Thos. P. Wilkinson, L.R.C.S.I., aged 74.

Wilson.—July 8, at Aberdour House, Fife, N.B., Sarah Liddell, wife of Robert Wilson, M.D.

AN ANALYSIS OF FIVE HUNDRED CASES OF PERFORATION OF THE MEMBRANA TYMPANI. (a)

By GEORGE P. FIELD,

Aural Surgeon to St. Mary's Hospital.

Perforation of the drum head is unfortunately a very common occurrence, and loss of hearing as a rule is the result. Deafness does not always take place, for some patients will be found to hear, perfectly well, even with a perforation of considerable size, while, on the other hand, a small aperture, may occasion very severe deafness. The size of the opening does not seem, in any way, to guide us in giving an opinion as to the amount of loss of hearing we may expect. The position of the perforation however will help us sometimes, for when we find the upper portion (Shrapnell's membrane) perforated, fortunately an uncommon occurrence, hardness of hearing is invariably the result, and necessarily the more the joints of the ossicles are interfered with, the greater will be the deafness.

Just a few words on the action of an artificial membrane and the improvement in hearing which takes place from its use. "If the continuity of the chain of sound conducting ossicles is destroyed, such as when the incus is detached from the stapes, resulting perhaps from a perforation, (as Hinton remarks) the most characteristic symptom of disconnection of the incus and stapes, is an inability to hear except during the act of listening." It is only by artificial pressure, such as that exerted by a moistened pellet of cotton wool, supporting the ossicula and restoring their continuity, that we can hope for an improvement.

I think it is now generally admitted by modern aurists, that the action of an artificial membrane does not depend upon the closure of the hole, thus confining the vibrations to the tympanum, as my predecessor at St. Mary's, Mr. Toynbee, pointed out. I merely mention this, because I think it helps us to understand more clearly, that a patient is not necessarily deaf when he has an openipg in the tympanic membrane, but invariably so, when the perforation, as it usually does, interferes with the proper function of the chain of ossicles.

After this digression, I will go back to my first point, that perforations are not uncommon. In looking through my list of cases, I find that on March 6th of this year, out of 100 cases under my care at St. Mary's Hospital, I had 29 patients with perforations in the membrana tympani, 12 of them double or perforated in both ears, so that taking both ears of the patients I had 41 perforations out of 200 ears.

If I had made notes of every case that came under my care, especially in hospital practice, I should have had a long series to analyze, but I have only taken those patients with a fairly complete history, the others I have considered valueless, for it can be readily understood that large numbers of every age and sex come to hospitals, with chronic discharge from the ears and perforated drum heads, who are unable to give anything like a complete history of their cases.

From my records of 500 cases, 118 had both ears perforated, and 382 openings in one ear, making 618 perforations in 500 patients. These I shall divide into two classes :—

(A) Those resulting from disease 420 patients, 106 of these double, making 526 perforations.

(B) Those caused from injury 80 patients, 12 of these in both ears, making 92 perforations.

To begin with Class A, those resulting from disease—I have no time to go into all the various forms of acute and chronic aural catarrh, their names even are legion, and as one form may run on to another, it therefore follows, that we rarely get similar cases ; just as we never see two people alike, they may be of one race, or even of the same family, with strong resemblance of features, but you never find two exactly identical individuals. And so it is with disease, you get the same class, features of a like kind, but rarely, if ever, the same symptoms. I want especially

(a) Read before the Harveian Society, May 20th, 1880.

to point out, therefore, that we must treat the symptoms of every separate case.

In taking perforation of the membrana tympani brought about by cold, I find I have 76 patients, 7 double, making 83 perforations—not counting those from bronchitis, acute rheumatism, or bathing, these I shall come to presently. Here we may have a multitude of causes and symptoms. A cold in the head may give rise to acute catarrh, which may lead to acute purulent inflammation and so on to perforation, but colds luckily, even in this charmingly variable climate, do not often run this course. Whereas in aural mischief from the exanthemata, we almost invariably get purulent inflammation and so necessarily perforation.

Just a few words on perforation of the drum head, in young children, from earache, which is very often a natural sequence of cold, because I think it is so frequently overlooked, and this neglect may lead, not only to a hole in the drum head, but to chronic otitis. In young children who are unable to speak, the diagnosis is sometimes difficult. Earache may be brought on from teething, whooping-cough, &c., but cold is the principal cause, and I am certain many children die annually from suppurative meningitis and abscess of the brain, brought on in this way, where in the majority of instances teething is said to be the cause of death. The child's gums have been regularly lanced, until death has put an end to its sufferings! And even if the ear mischief is diagnosed, I am afraid "the doctor sometimes stands by, and says to himself, 'It is a common gathering from which we shall get no relief until suppuration is established.'" (*a*) The diagnosis I have said is difficult, but if you touch the tragus the child will scream with pain, and I have found that it always refuses to lie on the affected side. Instillation of warm water into the ear will afford instant relief, and the little sufferer will generally go to sleep. A leech or two in front of the tragus with some calomel at night, and the frequent use of warm water or steam to the ear is the best treatment; poultices should be avoided. The Politzer air-bag should be used, for by inflating the tympanic cavity the secretions are allowed to escape through the Eustachian tube.

Any undue exposure to cold may lead to acute catarrhal inflammation and so on to suppuration and perforation of the membrana tympani.

Besides the 83 perforations I have already mentioned arising from cold, I have had 3 dependent upon acute rheumatism, 1 double, making 4 perforations, 2 in consequence of bronchitis, and 8 from bathing, making a total of 98 perforations out of 618, or nearly 1 in every 6 from cold.

Authors have divided acute inflammation of the middle ear into acute catarrhal and acute purulent inflammation. The catarrhal form may be the precursor of thickening of tissue, for mucus rarely makes its exit through the membrane, but on the other hand, remains in the tympanum, accumulates and lays the foundation to thickening of structures. Mucus, however, usually escapes through the Eustachian tube, and sometimes it becomes absorbed.

If we desire to get rid of the mucus and puncture the membrane, we often give exit to a jelly-like looking substance.

Acute catarrhal inflammation, however, is often a forerunner of the purulent form, and when pus is created, we have a much more destructive type of inflammation, and the membrane nearly always gives way. Thus we get spontaneous rupture of the drum head in the exanthemata. Scarlet fever heads this list with 217 patients, 70 double, making 287 perforations, or nearly half of the whole number from whatever cause. Measles 79 patients, 16 double, 95 perforations, or nearly a sixth of the whole. The symptoms of acute purulent inflammation are important, from its tendency rapidly to destroy the tissues of the ear, and lead to suppurative meningitis, abscess of the brain, pyæmia, and death. It generally begins with a tickling sensation somewhere between the Eustachian tube and the ear, or running from one to the other, deep seated pain increased by swallowing, talking, and sneezing; the pain extending over the whole of the side of the head to the eye, until the patient becomes almost frantic from the intense suffering, but is immediately relieved should spontaneous rupture of the drum head occur. If this does not take place, we sometimes get vertigo and delirium due to the pressure of pus on the labyrinth. The drum head is intensely congested, red, and swollen, and usually found bulging in its posterior half. Should this be so, the surgeon ought invariably to puncture. The best point to perform paracentesis of the drum head, is in its posterior inferior portion, for here the pus will drain away more easily.

It is worthy of note, that mucus in the tympanic cavity does not cause bulging of the membrane, pus invariably does, if allowed to remain long enough (Burnett), therefore, as a rule, if it is seen, puncture. In the *British Medical Journal* of May 8th, 1880, Mr. Robert Torrance, of Newcastle-upon-Tyne, gives us an instructive case of the kind, and shows the advantage of paracentesis of the membrana tympani.

The operation is easily carried out, there is not the slightest risk if it be properly performed, and it moreover immediately relieves the tension and pain, and causes evacuation of the pent up pus. It is an operation that is essential when leeches have been applied freely, and have failed to afford relief.

Local blood-letting if it is resorted to early enough, will generally he found to aid the patient, to alleviate all pain and thus prevent suppuration—just as certainly as the administration of even large doses of opium will fail to ease, without local depletion. In some cases of scarlet fever paracentesis would save the life of the patient, and we should not so commonly get total deafness, if medical men would only perform this trivial operation in time, and thereby arrest frightful destruction of tissue. Mr. Hinton was of opinion that the mortality from this disease might be considerably lessened, if a little more attention were paid to the ears. (*a*) It seems to me that, generally speaking, medical men never think of looking to possible aural mischief, until a discharge is but too evident. And when this has been established, patients are coolly instructed they will "grow out of it." Mothers of totally deaf children have over and over again come to me with four or five little bones—the ossicles—and these have been brought away by an unchecked, unheeded suppuration from the ears. The parents have always been told this same tale; varied occasionally by being advised by no means to allow the discharge to be driven on to the brain. These facts speak for themselves, out of these 500 cases I have had 4 deaths from cerebral abscess, and one very severe case of pyæmia. The latter would in all probability have died, had it not been for the unceasing care bestowed upon the case by my colleague Dr. Handfield Jones. Of the deaths 3 resulted from scarlet fever, 1 occurred after measles, and the pyæmia case originated from a fall on the head. Some of these fatal issues might I feel sure have been avoided, if in the first instance timely treatment had been adopted, and the same may be said no doubt of the complications I am about to relate, all of them being a direct consequence of chronic otitis.

There were 16 cases of mastoid abscess and caries of the temporal bone, some of these have been in extreme danger of their lives; seven of them following scarlet fever, 7 from cold, and 2 from unknown causes.

Forty-one aural polypi—29 after scarlet fever, 2 from measles, 2 from cold, and 7 following injuries.

CLINICAL NOTES ON THE SYMPTOMS OF HYDROPHOBIA, AND THE IMPORTANCE OF THEIR EARLY RECOGNITION IN THE LOWER ANIMALS.

By J. CARTER BATTERSBY, M.B., B.Ch., &c.,
Dublin University.

THE following cases of hydrophobia came under my observation within the last two years. Having noted at the time of their occurrence the symptoms that presented themselves in each case, I thought it would not be uninteresting to have them published.

CASE I.—Esther C., æt. 5½ years, a healthy-looking little child, was bitten on the forearm by a dog on April 5th, 1878, the animal being destroyed a few hours afterwards by the police. As nobody claimed ownership to the dog it was impossible to gain (in this case) any knowledge regarding its previous history. A short time after the girl received the bite the wound was cauterised with chloride of zinc, and no bad symptoms occurred until Sunday morning, June 30th, 1878, when the child became peevish and fretful, refusing to eat or drink anything. The wound on the arm became sore, and on the following Thursday morning, July 4th, about 10 o'clock, she was brought to hospital as a case of convulsions which had come on during the night. A few minutes after admission to hospital I saw the child. She was sitting on the mother's lap partly covered by a heavy cloak, and so little at the time seemed the matter, that I was inclined to doubt whether she was really ill. I was not, however, kept long in suspense, for on lifting up the cloak to feel her pulse she was suddenly seized with a violent spasm, but soon became quiet and happy-looking again. The mother now told me that the child had been bitten in April, by a dog, and showed me the sore arm which presented a crescentic-shaped wound about an inch in breadth, the edges of which were inflamed and the surface covered by a scab. The thought of hydrophobia naturally flashed across my mind, and I ordered the child to be put to bed. As she lay in bed, with a peculiarly bright and pleasing expression of countenance, she would suddenly be seized with a violent spasmodic attack, coming on spontaneously, or excited by a slight touch, or current of air, or the attempt to swallow anything liquid. During the attack all muscles, and especially those of the larynx, would become suddenly convulsed, the mouth open, the face distorted, turgid, and the eye-balls protruding from their sockets, different forms of squint at the same time being produced, one eye rotated in whilst the other maintained its natural position, or both being turned in together. The child would toss her head from side to side, staring wildly and anxiously about, now and then crying in a peculiar manner. Soon, however, she would become composed and even laugh, and play with some toys that were given her, the face assuming quite a happy appearance. Suddenly the child would commence crying, being evidently terrified at some imaginary object, but soon every fancied object of terror disappears, and she once more amuses herself with her playthings, laughing and talking pleasantly to herself. Some milk was now given to her to drink, which she tried eagerly to do by filling her mouth, but was immediately seized with another attack, a quantity of saliva which appeared thick and viscid streaming down each side of the mouth. When she again lay quiet, neither the pouring of water from one vessel to another, nor the sight of it, nor the reflection of any bright object would bring on an attack, but the slightest current of air occasioned by lifting the bed-clothes or from a partly opened window (although the day was intensely warm) would renew the spasms, which increased in frequency during the day, the respiration becoming very quick, the lips and tongue dry, and the teeth covered with sordes. At ten minutes after three the same evening the patient died, evidently from exhaustion. At the post-mortem examination made next day, the membranes of the brain and spinal cord were found to be congested. The lining membrane of the fauces, œsophagus, and trachea, was more or less vascular, and the lungs somewhat congested. The brain and spinal cord were sent to London for further investigation.

CASE II.—David M., æt. 70, a strong, healthy-looking man of temperate habits, was bitten on the upper lip and slightly on the nose by a pet terrier dog, on Saturday evening, May 8th, 1880. The wound on the lip bled a good deal, and the patient sucked it for some time. About an hour afterwards the lip and nose were cauterised with nitrate of silver. On Tuesday morning, June 2nd (on the 24th day after receiving the bite) the patient got up in his usual good health, and on pouring the water into the basin in order to wash, he suddenly felt as though his arms were paralysed, and was unable to perform his customary ablutions. He immediately acquainted his family of the fact, and seemed perfectly conscious. Shortly afterwards he sat down to breakfast, and felt afraid to swallow either solid or liquid food, the slightest attempt to do so making him, as he says, "feel too nervous." He now—viz., Tuesday, June 2nd—went to bed, and commenced wandering in the most incoherent manner, imagining that some soldiers and a dog are in the room, his delusions sometimes making him believe that people or animals are outside of the ceiling and that he cannot get at them. When his own people enter the room he thinks them changed in appearance.

The above narrative I was given by the patient's daughter, and my friend Dr. Hewetson, of Clonmel, with whom I saw the case, assures me that on Tuesday, having a strong suspicion as to the nature of the disease, he fanned him with his hat, whereupon he was seized with a violent spasm, all the muscles becoming suddenly convulsed. On visiting the patient this morning (Thursday) two days after the first symptoms appeared, I found him *sitting up in bed* apparently quite rational; he informed me of what the doctor had done and seemed displeased with him, as he said "the fanning made him nervous." After a short time, however, I noticed the patient beginning to speak in rather an incoherent manner, and having entered on some topic of conversation he seemed reluctant to let me leave until I heard it all. Whilst speaking, or even sitting quietly in bed, he would suddenly shudder, at the same time drawing in a long inspiration and seeming afraid to let the air out of his chest, and when so doing would produce a peculiar sound (which is most difficult to describe) resembling somewhat the word *bou*, his cheeks at the same time being puffed out. The same phenomena would be produced by drawing up the window blind. He felt confident that he would be "all right" by the following Monday, never to his recollection having been confined to bed through illness, his only complaint being slight pain over the heart and epigastric region. I now brought him some milk in a cup and asked him to drink it, which he reluctantly did, but little spasmodic action being brought on; about fifteen minutes before he had taken gr. xxv. of chloral hydrat. On Friday morning his condition was much the same as on previous day. He told me he had "slept well during the night and felt greatly better, but the thought of drinking anything made him feel quite nervous." I now noticed that his voice had become hoarse and husky. About 7 o'clock on Friday evening I again saw the patient. His pulse, as on the previous day, was 120 per minute, soft and regular. His respiration was 18 per minute, and temperature 98·7, his tongue was moist, slightly furred, the tip and edges being rather red. His people informed me that during the day they found more difficulty in getting him to take food, "and on several occasions he attempted to bite the cup," an action, however, which I failed to witness. I now tried to get him to drink some whey, but he told me that it would make him "too nervous," and the very thought of so doing made him shudder; however, with a little coaxing I got him to take the cup in his hand, when with a most painful effort and trembling which caused some to be spilt, he got it to his mouth and with a few

gulps swallowed the contents. He immediately seemed much excited, and abused his brother who happened to enter the room for making him drink. Now, as on previous occasions, he got gr. xxv. of chloral hyd., and gr. xxv. of bromide of potash, to try and allay the excitability which on the previous day was so great that on getting his attendant out of the room, he got out of bed and followed me downstairs, but with a little remonstrance I persuaded him to go back, which he did quietly. On Saturday his symptoms were more marked than on any other occasion on which I had seen him. His face had an anxious and bewildered look, his colour was more dusky, the conjunctivæ of both eyes were injected and the pupils contracted, his appearance was not unlike that of a patient in typhus fever. His tongue was quite moist but slightly furred, and now for the first time I noticed his mouth full of saliva, which appeared thick and viscid; he was more excited than when last I saw him. On Sunday I visited the patient at 2, and found him lying quietly in bed; he spoke quite rationally, but soon commenced rambling in a strange manner. I now asked him to take a drink and *he raised himself in bed and prepared to do so*, saying at the same time, as on previous occasions, "that he would rather not, that it made him too nervous." Immediately on seeing the *bright tin vessel* which contained some milk, he was seized with a spasmodic nervous shock (like what one experiences on suddenly stepping into cold water, or having it poured on the back) drawing in several inspirations and turning his face away; the sight of water had the same effect. In about half a minute he recovered, and with his face still turned, seized the vessel with trembling hands, asking at the same time "not to hurry him," and with an evident feeling of dread swallowed a few mouthfuls which he soon after vomited no spasm now being produced after drinking. His pulse was still 120, respiration 18, but his temperature had risen to 103° since previous day. Hyperæsthesia was now well-marked, the patient being much affected by the current of air caused by lifting up the bed-clothes. For the first time he complained of a burning sensation in his mouth, and the muscles on the left side of the face seemed partly paralysed. About 7 o'clock the same evening he got drowsy, and died in a comatose condition at 2 o'clock a.m. on Monday morning, 138 hours after the first symptoms had set in. It was impossible in this case to make a post-mortem examination, the patient being a respectable business man in the town of Clonmel.

It is a fact worthy of no small amount of notice that a peculiar change was recognised in the dog a few days before he bit his master. He became sullen and restless, often running up and down stairs, not remaining long in any particular place, and licking the boards about the house. His appetite failed, but his thirst increased, and he even drank some milk the Sunday evening after the man was bitten. His bark was especially noticed as peculiar, so much so that the children about the town tried to copy it; this peculiarity was thought to be the result of pain, and on Monday morning he was drowned. Through the melancholy ignorance of the importance to be attached to, and the danger of the above symptoms (although fully recognised) the owner took the dog on his knee, when suddenly he snapped and inflicted the wound which caused his master's death. The following symptoms have been described as diagnostic of rabies in the dog. These are, "unusual sullenness, fidgeting, and continual shifting of posture, a peculiar delirium, the dog perhaps springing up and giving an angry bark at some imaginary object. But if his master speaks to him every fancied object of terror disappears, and he crawls towards him with his usual expression of attachment. Then comes a moment of actual vacuity: the eye slowly closes, the head droops, and he seems as though his fore feet would give way and he would fall; but he springs up again, every object of terror once more surrounds him, he gazes wildly around, he snaps, he barks, and rushes to the end of his chain to meet his imaginary foe. The amount of ferocity displayed by rabid dogs seems to vary; some if loose rush out, biting every man and beast in their way, others show an increased fondness and are perpetually trying to lick their owner's hands and face. Another early and constant symptom of rabies is a peculiar change of voice. There are two sounds in particular that deserve notice, one of which is described as a hoarse inward bark with slight elevation of tone, the other a peculiar combination of a perfect bark, ending abruptly and very singularly in a howl a fifth, sixth, or eighth higher than the commencement. Other symptoms observed at the commencement of the disease are, loss of appetite, propensity to lick cold surfaces; there is no dread of water, on the contrary, an insatiable thirst; the mouth is dry, and the saliva exceedingly viscid. The usual duration of rabies is from four to six days."

It is not my intention nor am I at present prepared to enter fully into the pathology and treatment of hydrophobia, an investigation being held in London for that purpose, which doubtless will throw much light on this obscure affection and probably be the means of suggesting remedies other than those which at present seem to have but little effect on this awful malady. However, I hope to show that we have within our power a means which, if carefully carried out and conscientiously practised by the public, would considerably diminish the number of cases of hydrophobia which are now annually increasing, so much so that we can scarcely take up a medical paper which does not record a death from that disease. What I would suggest is that the public should have every opportunity afforded them of learning, and thus being able to recognise, the early symptoms of rabies in the lower animals, and the proper and *immediate* treatment of wounds inflicted by the same. Such might easily be done through the public press, in our daily papers, and by the Local Government Board or other influential body having notices printed in red letters describing plainly the early and prominent symptoms of rabies, and cautioning people when such symptoms appear to have dogs or other animals destroyed, or tied up for six days until further symptoms show themselves or existing ones entirely disappear. That such notices be sent to the different dispensaries or medical institutions, from thence to be distributed and posted throughout the country—villages and towns. By this means, which could as easily be carried out as the distribution of notices telling the country people the different places at which the dispensary doctor will attend to perform vaccination, many a valuable life might be spared the awful death of hydrophobia, arising it may be from the bite or scratch of a pet cat or the lick of a favourite dog which for a few days had exhibited signs of an increased fondness for his master or become notably changed in his ordinary habits.

THE PHYSIOLOGIST IN THE HOUSEHOLD.

By J. MILNER FOTHERGILL, M.D.

PART I.—ADOLESCENCE—(*continued*).

(*Continued from page* 69.)

PROBABLY this is more true of girls even than boys—however revolting the idea may seem to some; and while the boy studies wild adventures, histories of pirates, stories of the Rocky Mountains, or of Eastern travel; the girl is apt to furtively read novels which tell her something about human passions—in a manner the reverse of desirable. The child will learn something on this subject, and the worst knowledge will be seized upon in lieu of something better. Long before the birth of sex there are oscillations of passion felt, and everything that can foster such premature feelings should be carefully avoided: but the existence of passions should not be utterly put out of sight. The restricted life and fettered mind of girls leave them with less to actively occupy their thoughts than is the case with boys. They are studiously taught concealment; and, betwixt the two, a girl may be a perfect model of outward decorum, and yet have a very filthy mind. The prudishness with which she is brought up,

leaves her no alternative but to view her passions from the nasty side of human nature. All healthy thought on the subject is vigorously repressed; so her secret mental workings are carefully concealed. Everything is done to darken her mind and foul her imagination; by throwing her back on her own thoughts, and a literature with which she is ashamed to own acquaintance. Nature cannot be expelled with a pitchfork, the Latin poet insisted; and this too prudish bringing-up of girls is at once stupid and irrational, while it frustrates its own aims. Concealment, as has been insisted upon before, is ever bad; it is a moral cancer which spreads and taints all around it: and it is opposed to a girl's best interests to prevent her from having fair and just conceptions about herself and her nature; and forcing her to seek the information—she is determined to acquire somehow—from sensational and often indecent novels; or, still worse from the vicious works which are advertised freely in newspapers which meet her everywhere. With the reports of divorce cases—where the courts are crowded with women brought up on the old plan here criticised—a girl is familiar with everything she is supposed not to know about. And the fact, however ugly and repulsive it may look, remains; and will not be annihilated by any desire, however strong, upon the part of her parents and instructors. The fact being there, it must be looked in the face, and encountered boldly; shutting our eyes, however closely, will not destroy or abolish it. The fact that a girl has certain promptings, certain subjective sensations, must be entertained by every parent and every schoolmistress. And the wisdom of the course still adopted, of declining to take the matter into consideration at all, is now gravely called in question. No domestic arrangements, no vigilance that can be exercised, can secure a girl from considering the sensations which it has pleased God to give her; they may make her view the matter from its least desirable aspect; but is that a result to be sought after? So far as modern education goes, a girl is left utterly helpless at the mercy of her passions when they are excited. There is no healthy control over them taught her by her educational course; and the most disastrous results follow any failure in the social arrangements which are set up for her protection; she has no inward strength of her own; virtue was preserved once by mechanical contrivances, now it is secured by artificial social arrangements The whole thing is rotten; as rotten as a decayed beam, and just as little to be trusted to or relied upon. That this strong expression is warranted by facts, is borne out by the testimony of our newspapers—accounts of girls running off with their fathers' grooms, to the utter ruin of all their future; of blackguards arraigned at our police-courts for the seduction and abduction of girls of tender age, too commonly seen; and for one that gets into the public prints twenty are hushed up in private, with what amount of family disgrace and sorrow the world little knows. What protection in herself, except the absence of passion, has the carefully brought-up girl of the present; reared in moral corsets, watched with solicitous care: a hot-house plant, forced by a heated immoral atmosphere, made vicious by an unsound system of education; which is as bad and as injurious as if it were the product of deliberate malice or fiendish malignity.

Our scheme of education should be such as to strengthen the moral fibre of a girl, until she possesses a power over herself of her own; which will be a tower of strength to her in the hour of temptation. She should be so trained as to have that power of self-command which is acquired by women of more mature age; and whichis recognised by permitting to older women a freedom of action which society sternly denies, and wisely too, to young women and girls. Many a fair young girl is irredeemably ruined on the very threshold of life, herself and her family disgraced, from ignorance as much as from vice. When the moment of temptation comes she falls without any palpable resistance; she has no trained educated power of resistance within herself; her whole future hangs, not upon herself, but upon the perfection of the social safeguards by which she is hedged and surrounded. What the consequences may be of an accidental failure in these safeguards is suggested by the stringency with which all social regulations are enforced. She is told to keep her body in subjection, and has the vaguest conception as to what is meant thereby; she is drilled into strict discipline as to the observance of social regulations; but she possesses no educated self-control against those times of temptation when the past and the future are as nothing in the balance compared to the imperative impulses of the present. Better far that girls should be educated to meet such temptation by a certain knowledge, even if this be somewhat repugnant to our Anglo-Saxon notions about women; than that she should be left to yield when the hour comes, and her virtue depend upon extrinsic forces, which may be put in abeyance by an accident that may occur at any time. Virtue by the present education is placed in a most precarious positionand; is only secured by the strictest avoidanceof any approach to temptation. Would it were not so! And nothing but entire revision in our educational arrangements for girls can give a girl a sure protection against her own passions. It is easy to be good in ordinary circumstances, as easy as the running of water along a hewn channel; it is those emotional periods, in the midst of conflicting passion and contending forces, when the line of action is like the rift in rocks rent by dynamite—which test the soundness of the character of the individual, and of the educational course to which she may have been subjected.

And now, finally, a few words addressed to the child-readers of this pamphlet. Whenever a child is in doubt as to whether what it is doing is right or wrong, let it ask itself the question, "Is this what I should like my father and my mother to know about?" Whatever their father and mother may not know is wrong—without any manner of doubt. Vice may be concealed, but it saps the moral character, and will leave the mind a shattered wreck; as bodily disease may leave the organism a crumbling ruin. A momentary action which may be curiosity rather than vice may lay in ruin the whole future of a budding child, boy or girl: all the efforts and self-denial of a long after life may be insufficient to efface a blot which perhaps was really rather thoughtlessness than deliberate action. Children have no power to represent in their minds the experience of the adult, or to conjecture all the dire consequences of actions, which scarcely seem important at the time. The future is veiled from them; and they perceive not what may be the consequential outcomes of their conduct—outcomes which are vividly present to their seniors who can look back on a past illumined by a long intense ray of personal experience. Having then no experience of its own, the child must be guided by some substitute for personal experience—it must take the word of those older than itself. Those who have its best interests at heart do not desire to see it marching forward blindly amidst dangers and pitfalls innumerable, unsuccoured and unwarned. This little essay is the result of much consultation by many interested in the welfare of growing children. It has been a difficult matter to write upon; but if one parent finds it lessen the difficulties of talking to his or her child, on the subject of itself, its development, and the birth of its passions, even in the smallest degree, the writer will feel satisfied. But if one single child will ever feel that it has been rescued from imminent peril by the perusal of this essay, he will feel more than rewarded.

Our weekly summary of the death-rate in foreign cities, from the returns of the Registrar-General, show that St. Petersburgh, Berlin, and New York have the highest death-rate at the present time of the cities of the world. Whilst the largest city in Christendom, London, maintains its average rate of mortality, that in the three cities mentioned is abont one hundred and fifty per cent. higher.

Clinical Records.

CASES IN PRACTICE.

Heart Affection Simulating Dyspepsia.

By JOHN W. MARTIN, M.D.,
Sheffield.

THE main interest of this case is centred in the mildness of the symptoms connected with the affection of the heart; these were so silght and so marked by the sense of flatulence and discomfort after food, that the case might easily have been passed over as one of simple dyspepsia, an error which would have led to most unsatisfactory results when the diagnosis was brought to the test of treatment.

Previous to the 8th of November, 1879, J. K., æt. 31, by occupation a butler, had always enjoyed excellent health. About that date he commenced to feel troubled with a slight sense of pain and discomfort just below the ensiform cartilage, and across the region of the stomach, the sense of malaise being greatly increased about two hours after eating. The feeling was one of flatulence, and great oppression in the stomach, only relieved by taking a little hot brandy and water, which caused him to belch wind, and so gave relief. The patient, it is but just to say, was most temperate in his habits.

I first saw him, November 29, three weeks after the onset of the attack. He came complaining of indigestion, and thought his liver was out of order. The first thing that attracted my attention, and caused me to doubt that the stomach was the offending organ, was the condition of the tongue, than which a healthier could not have been presented to my notice. It was firm, clean, and moist. I found that when the patient had fasted for some hours he had a healthy desire for food, the first portions of which were eaten with relish; he was, however, soon satisfied, and the effort to eat the amount he had usually been accustomed to was followed by a great increase of pain and discomfort. The latter, also, were constant, although varying in severity. The bowels acted regularly, the motions being healthy in character. Water, normal in character, was passed freely. There were no acid eructations. Altogether I felt that the case could not be passed over lightly as one of dyspepsia.

On making further inquiry, I found that whilst feeling strong when at rest, yet he was unable to undergo any unusual exertion. Running up stairs, walking against an incline, or attempting to lift heavy weights, induced dyspnœa, palpitations, and slight attacks of vertigo. This history led me to inquire into the state of the lungs and heart. As for the first, I found them healthy in every respect; not so, however, with the latter. Cardiac dulness was much enlarged, measuring three and a-half inches in the vertical direction from the upper border of the fourth rib on the left side, at a point one and a-half inches to the left of the left margin of the sternum; and four inches in the lateral direction from a point mid-sternum, opposite the articulation of the fifth rib, over towards the left side, passing under the left nipple. There was decided *fremissement* on placing the hand over the heart; the impulse of which was weakened and diffused. The character of the heart sounds were altered; *the first* was faint and distant, almost marked by a loud friction murmur, heard equally diffused over the whole area of dulness; this murmur being synchronous with the cardiac systole; *the second* was loudly accentuated. There was neither murmur or friction sound to be heard over the base of the heart. The action of the latter was very irregular, both as to force of impulse and rythm; occasionally intermittent. The patient slept badly and dreamed heavily; he was a married man, with one child, and, as I have already said, exceedingly temperate in his habits; he had never suffered from rheumatism, nor could he give me a history of gout or rheumatism in his family; he never suffered from venereal disease of any description. The most careful inquiry failed to elicit any history of primary chill and rigor, or any marked febrile constitutional disturbance.

I commenced the treatment with grs. viii. doses of iodide of potassium, combined with M x. doses of tr. aconiti every fourth hour, and applied a blister 4 × 4 inches over the præcardiac region, to be allowed to remain on for eight hours from the time of application.

Dec. 2nd.—Felt much better; blister had risen well. The pain complained of was greatly diminished. Heart's action improved, both as regards force and regularity. There was but slight diminution in the area of dulness. Friction murmur not nearly so marked as before. Treatment continued.

8th.—Improvement continues, but progress slow. Applied another blister over the heart, to be left on for six hours, and substituted M xii. doses of tr. digitalis for the aconite in the iodide of potassium mixture.

10th.—Much improved; area of dulness diminished; heart's action much stronger and steadier, capable of enduring a greater amount of exertion without experiencing dyspnœa and vertigo; and the tendency to palpitations had become much less marked. A light but well-marked pre-systolic mitral murmur was heard towards the apex, its point of maximum intensity being at the point of impulse, two inches below the left nipple; this murmur was also heard very distinctly upon carrying the stethoscope a little backwards, and slightly upwards towards the axilla. The friction murmur, previously described as being generally diffused over the area of cardiac dulness and synchronous with ventricular systole, was greatly diminished in intensity, and seemed as if about to disappear altogether. Treatment continued.

17th.—Almost himself again. Suffered no longer from vertigo or palpitations, from which he had suffered so much in the earlier part of the attack in exerting himself. A slight sense of dyspnœa, however, remained; heart's action had become strong and regular. The sense of pain and discomfort after meals no longer felt. Friction, murmur, and *fremissement* quite gone. Area of cardiac dulness was reduced to 2 × 2 inches, which we may regard as fairly normal. The pre-systolic murmur existed unchanged, but apparently caused him no special discomfort, since in every other respect his general health seemed much improved. His subsequent history may briefly be summed up as one of steady improvement and convalescence. I examined him again in June, 1870, with the exception of the pre-systolic murmur, which existed unchanged; his health seemed all that could be desired. I last met him in July, 1874, when he still remained in excellent health. I made no examination, as the meeting was a chance one in the street.

The Mineral Waters of Europe.

ANALYTICAL REPORTS ON THE PRINCIPAL MINERAL WATERS, FOR THE GUIDANCE OF THE PROFESSION AND THE PUBLIC.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,
President of the Pharmaceutical Society of Ireland, &c.

WITH NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,
Lecturer on Materia Medica and Therapeutics at the London Hospital.

(*Continued from page* 73.)

IN our last article we drew attention to the fact that the mineral waters of England and Ireland were very considerably underrated by the medical profession. This undesirable, and we may say, unpatriotic state of things, has been induced, no doubt, by the very proper value which the medical man attaches to climatic influences and change of scene—items which should not, for a moment, be considered unimportant—but now that the bottling of mineral waters has become such a special trade, we see no just cause why English waters should not compete in this direction. The names of many foreign, but inferior waters, are well known in this country, and largely run after.

Candellé, in his useful *Manuel Pratique de Médecine Thermale*, 1879, disposes of the English waters in about six lines. He says, *L'Angleterre est un des pays les plus*

pauvres en sources médicinales. It will be part of our programme to dispell this illusion. His book is instructive as showing that even in the present day faith forms a very important factor in *Médecine Thermale*, as practised on the Continent.

We have now to speak of a class of waters which are often spoken of in medical works as unimportant, that is, of indifferent waters, or waters in which the therapeutic action is not sufficiently pronounced to be used in the direct treatment of disease. Some of these waters may contain infinitesimal quantities of ingredients, which by their constant use might produce remedial effects; but it is their use as potable waters, or for table drinking, that from our view renders this section of mineral waters most important. The great increase in the use of mineral waters in everyday life is desirable, providing we can insure that the water is perfectly free from organic impurities, and providing that the mineral matters are sufficiently definite in character.

The mineral salts in a table water should not, as a rule, much exceed 1,000 grains per gallon. When it exceeds this quantity it should not be indulged in too freely. All waters should be used judiciously, according to the idiosyncracy of the consumer, and the peculiarities of the water. The medical man is the proper person to determine this point: another of the many reasons that the mineral water question should be put definitely before our readers.

The remarks made in connection with the presence of nitrogenous organic matter in sulphurated waters or chalybeate waters, apply with double force in the case of these potable waters—waters which are drunk freely and constantly—and it is absolutely necessary that a water which becomes an inmate of our house should be like Cæsar's wife, beyond suspicion. In the days of Liebig, and even in the early analyses of Fresenius, these points were not sufficiently investigated, and it is our intention to re-investigate analyses of that period. In some waters we find that very full and careful analyses have lately been done by men of acknowledged celebrity. In such cases we will give the most recent and careful analyses, stating at the same time our authority.

Directly we accept the desirability of using a mineral water in its potable sense, we must at once consider it simply as a food product, and, therefore, the nearer it resembles the mineral constitutents of the blood the more generally it may be relied upon.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 20, Bombay 28, Madras 33; Paris 30; Geneva 26; Brussels 21; Amsterdam 23, Rotterdam 21, The Hague 19; Copenhagen 24; Stockholm 29; Christiania 27; St. Petersburgh 52; Berlin 52, Hamburg 24, Dresden 28, Munich 38; Vienna 27, Buda-Pesth 32; Rome 25, Naples 36; Alexandria 46; New York 49, Brooklyn 38, Philadelphia 35, and Baltimore 27 per 1,000 of the populations. Small-pox caused 41 more deaths in Paris, and diarrhœal diseases 506 deaths in Berlin.

Department of Lunacy.

"MEDICAL PRESS AND CIRCULAR" SPECIAL COMMISSIONER'S REPORT ON PRIVATE LUNATIC ASYLUMS.

Introductory.

For a very long time a determined opposition has been maintained against the existence of private lunatic asylums, the leaders of the movement being willingly seconded in their efforts to repress these institutions by ignorant writers of sensational articles in the lay press. It is easy to comprehend the feeling which dictates the action of the general public in this matter, the source of information whence they are enabled to gather opinions having rarely up to the present time been other than that contained in over-wrought and highly imaginative pictures of an unreal condition of things; or in the expressions of those who have by inattention or inaptness long ceased to speak with the authority of unbiassed judges. We have in consequence been in the last few years flooded with a mass of literary productions, dealing with the questions of lunacy law reform, the care and control of the insane, the relative advantages of public and private asylums, and kindred subjects, the whole tendency of which has been destructive of the confidence and trustfulness in the *bona fides* of private proprietors that an intimate acquaintance with their aims and methods convincingly inspires. It is unnecessary to recapitulate here the charges laid to the door of private asylums; enough be it to recall them to the recollection of the reader; their refutation will be wrought out in detail as this series of articles progresses.

Foremost among those who seek to overthrow private asylums, and merge them in the public establishments, which seemingly are alone thought capable of effecting any calculably good results, Dr. Bucknill's name is prominent. This gentleman was for a considerable length of time a Chancery Visitor in Lunacy, and few more than he are by experience acquainted with the workings of our lunacy system, and qualified to estimate their shortcomings and advantages. It is, therefore, the more inexplicable that Dr. Bucknill should show himself so grievously forgetful of the details which render the arrangements he denounces especially beneficial. Impossible as it must be to infer any bias on his part towards any but the most valuable systems of relieving lunacy, his determined attitude of opposition to the extension of plans that have worked admirably in so far as they have been experimented with, remains a very perplexing *crux* in the history of the lunacy question. Dr. Bucknill insists that private asylums are inferior places of confinement for persons of insane mind as compared with Government institutions; that the temptation to maltreat and unduly detain for the sake of profit is one to which private owners are peculiarly susceptible; and in a fashion that exhibits the most ungenerous disposition, he stigmatises private asylum proprietors as rapacious and cruel, regardful of the purses of their patients, forgetful of their true interests, and animated only by sentiments characteristic of brutality and greed. By the sensation-mongers, ready always to accord belief in the lower qualities of humanity, and prepared by the traditions of the past to anticipate the realisation in the present of scenes and horrors impossible to be found under any existing *regimé*, the accusations have been ably seconded with expressions of loathing and horror utterly unworthy of the actual facts. Careless as the unlettered ever are to investigate the truth or falsity of any statement presented to them, rushing headlong to accept the piquant morsel carefully seasoned to act as an agreeable stimulant to morbid curiosity

and crude belief, there is small wonder in the fact of their receiving the nonsense that successfully tickles their expectant fancy. With the other better informed sections of society, however, the case is different. That they should without inquiry lend themselves as parties to the deceit that has been practised, reflects disgracefully on the honesty and truth usually ascribed as the heritage of our cultured classes. It may be argued on their behalf, however, that the blame is less to them than to the teachers who, wilfully or negligently, have omitted to lay bare the truth, choosing rather, so to dress and cloak it, as to induce the most unfavourable judgment in matters of important detail. The universal horror of madness, the fear connected with its consideration—a fear that has been nurtured through generations of ignorance—have combined to maintain the ill-considered and unjustifiable mystery with which the question of asylum management is shrouded.

In the interests of humanity and of justice, the time has come at which it is imperatively necessary that false views hitherto cherished, shall receive a final and decisive blow. The dense darkness surrounding the question of the detention and treatment of lunatics in private mad-houses, is one that involves the comfort and well-being of English society; the shame of it is inseparable from the density which distinguishes it; with the illumination of the one, the magnitude of the other can alone be diminished, and the natural candour and honest impartiality of the British nature can be trusted to discriminate unrighteous persecution and unmerited censure.

In pursuing the plan laid down to be followed out in this report, it will deal with the question under three general heads, viz. :—

I.—Commital.

II.—Detention and treatment.

III.—Inspection.

It will then further proceed to compare the methods under which the treatment of patients is conducted according to existing regulations, and to exhibit the fallacious and untenable nature of the arguments advanced to demonstrate the superiority claimed for "mass" treatment in contra-distinction to the family influences that are principally relied on in the institutions termed private asylums. No effort to allure by sensational descriptions will be made; too much mischief has been already effected by the questionable guise under which a medical contemporary has admitted articles condemnatory of private asylums to its pages. The wisdom of appealing to the excitable among mankind by such titles as "The Power of the Keys," "Why, this is a Certificate," "The Prerogative of Asylumdom," "Under which King, Bezonian?" &c., &c., is at best only an equivocal device for propping a weak and indefensible cause. Throughout the whole of his essays against that to which he personably objects, Dr. Bucknill has exhibited an unfortunate partiality for the employment of sensational writing that goes far to deprive his severest strictures of the force they might else possess in the eyes of an unimpassioned judge. It cannot be too much insisted on that the question now to be decided is no mere personal one, or even one of simple opinion; it has attained a dimension and importance that combine to make it "national;" the ultimate fate of thousands of helpless irresponsible beings will depend on the immediate action of the legislature in relation to them, and the decision that eventually determines the lines on which that action shall be pursued must be watched with the jealous eye of disinterested right. The entire subject is capable of receiving a calm and judicial deliberation, conducted on a basis of scientific accuracy. The attainment of this end is not to be sought by means of rabid invective or indiscriminate abuse. The aim to be steadily kept in view is that which in recent discussions has been too frequently lost sight of—namely, that it is the amelioration of the condition of a distressed class of beings, and not, as is assumed by the opponents of a system, the desirability of retaining or abolishing this or that system. The object of retirement on the part of the insane is that they may recover their mental equilibrium as speedily as possible by being placed under conditions most likely to favour this consummation. On the one hand are displayed the advantages following the discipline and regularity associated with official espionage and official routine; on the other side are exhibited the alleviating influences of a system in which the home life of the individual rules paramount, and friendly and constant association with mentally normal persons is most depended on to secure the desideratum common to both plans, *i.e.*, the restoration of the patient. The absolute freedom of action, the assurance of untrammelled intercourse on terms of social equality, lamentably absent as these are, and must be, from governmental institutions, are a pre-eminent feature of the treatment characterising the private in contra-distinction to the public establishments. The surest mode of convincing the uninformed on this point would be for them to acquaint *themselves* with the truth of that which is asserted, by actual inspection of the condemned asylums. Unfortunately this cannot be hoped to take place, the widespread horror of madness being a fatal bar to the procedure here suggested. A faithful chronicle of that which does occur, *a record* of what has been witnessed during *residence* in more than one private asylum, and of visits paid under conditions that have enabled a true picture to be drawn, will be the best available means of offering opportunities for universal judgment on the question of asylum management. It is a matter of regret that statements so far from the truth should be accepted, as are those which have found their way into the minds of the people. The future of asylums rests with them; the only object held in view in these papers is the encouragement of truth—*magna est veritas et prevalebit*.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 7TH, 1880.

Dr. W. S. PLAYFAIR, President, in the chair.

UTERINE FIBROID.

Dr. CHAMPNEYS showed the uterus of a woman aged 69. The posterior wall was occupied by a fibroid which had extended into the posterior lip of the cervix and far below the level of the os externum. The rest of the uterus was not thicker than a double sheet of blotting paper, this atrophy affecting the cervix also. In the right broad ligament was a fibroid calcified "*en coq*," the size of a large tennis ball.

RUPTURED TUBAL FŒTATION.

Dr. GODSON showed the uterus and appendages of a woman aged 22, mother of two children. While sitting at work she was suddenly seized with violent pain in the lower abdomen, and became faint and pallid. Mr. Henry Thompson, of Hull, who saw her in the course of an hour, found her in a state of collapse, and almost pulseless, and she died in eight hours. At the autopsy Mr. Thompson found the abdomen full of blood, amounting to at least six pounds. The specimen showed the right Fallopian tube distended by what seemed to be a fibrous clot, and in this situation a rent had taken place. The uterus was lined with decidua, and a mucous plug occupied the cervix. The woman had menstruated six weeks previously.

Remarks were made by Dr. Wiltshire, Dr. Savage, Dr. Rogers, Dr. Champneys, and the President.

REPORT OF COMMITTEE ON DR. CHAMBERS' CASE OF HYSTERECTOMY.

The tumour measured 9 by 8 by 4¾ inches, and on section was found to be a large fibroid uterus. The fibroid was situated above the cavity, into which it bulged. In its lower third it was intimately connected with the uterine tissue.

In reply to Dr. Potter, Dr. CHAMBERS stated that the patient had done well.

LADIES SANITARY TOWELS.

Dr. GALABIN showed the new sanitary towels manufactured by Messrs. Southall and Barclay, of Birmingham, as a substitute for the ordinary diapers, for use during the catamenia and after confinement. They contained a pad of absorbent cotton wool, rendered antiseptic by boracic acid, as being less irritating than other antiseptics. The advantages were that they could be burned after use, and so were especially valuable for the lying-in room, and that they were very soft and absorbent. The retail price was 3s. a dozen, and it was believed that the cost would not much exceed that of the washing of ordinary diapers, since they could be worn longer. The wholesale agents in London were Messrs. Sharp, Perrins, and Co., 31 Old Change.

ADJOURNED DISCUSSION ON DR. GRAILY HEWITT'S PAPER, "REPORT ON SIXTY-SEVEN CASES OF UTERINE DISTORTION OR DISPLACEMENT TREATED DURING SEVEN YEARS AT ALL SAINTS' INSTITUTION FOR LADIES."

Dr. BANTOCK expressed his high estimate of the value of the paper, and considered not its least merit to be the prominence given to the doctrine that deviations of the uterus are directly or indirectly the cause of much, though variable, constitutional disturbance as well as local suffering. It was an encouraging fact to those who accept this doctrine, that, however determined was the opposition ten or fifteen years ago, it had gradually got less and less as time had advanced. It was still maintained by some, as by Scanzoni, that flexions and versions are of no importance, unless complicated by an alteration in the texture of the organ. The evidence adduced by Scanzoni, in favour of this view, was of the weakest kind, and, moreover, the chief result of displacement was that very alteration of texture, to which so much importance was attached. It was admitted that sudden displacement of a healthy uterus generally produced marked symptoms, and he had never seen a case of well-marked retroversion, retroflection, or anteflection without some symptoms referable either to the menstrual periods or intervals. He thought that the distinction between version and flexion was not always maintained by the authors of standard works, as Dr. West and Dr. Barnes. He could not, however, follow Dr. Gervis in his classification of cases of retroversion into three varieties, since he thought it could serve no useful end in practice. It was more important to recognise the difference between retroflection and retroversion, and he was in the habit of regarding the position and direction of the cervix as the chief test. If the os pointed towards the pubes, or even toward the vaginal outlet, the case was essentially one of retroversion, though there might be a bend whose concavity looked backward. In his own practice, out of 149 cases of uterine displacement, 72 had retroversion, 51 anteflection, 21 anteversion, and only 5 retroflection. He believed that Hodge's pessary had no direct action on the body of the uterus, but acted by drawing the cervix backward. This was the only appropriate treatment for retroversion. Retroflection, on the other hand, could only be treated satisfactorily by some such instrument as Meadows' compound stem. In some cases of retroflection, also, in which the flexion was very pronounced, some form of intra-uterine stem was ultimately required. Dr. Goodell, of Philadelphia, had recently withdrawn his condemnation of the intra-uterine stem.

Dr. ROGERS remembered one of their past presidents stating that he never used a pessary of any kind, believing them to be dangerous instruments. He had himself found pessaries, especially the Hodge and Zwancke, of great use in displacements and fallings of the womb. Our greatest authors were gradually admitting that flexions and their consequences play a most important part in the causation of dysmenorrhœa and other chronic sufferings. He thanked Dr. Graily Hewitt for pointing out the necessity of treating displacements. He thought it an evil, however, to keep patients so long recumbent. He had also long ago been obliged to discard the cradle pessary, on account of the mischief it caused, especially in married life. Adopting careful preliminary treatment, he had found Dr. Greenhalgh's elastic stem, as well as that of Dr. Wynn Williams and others, give great relief. Up to this moment he had not had a fatal case, and only one or two where the instrument was not well borne.

Dr. SAVAGE said that argument was scarcely needed to show the propriety of using stems for uterine deviations, when they really were the cause of suffering, which often was not the case. Pessaries without stems merely kept the uterus out of the vagina. But on a former occasion he had brought to the notice of the Society nine cases of death caused by stems, death in each case being due to rapid peritonitis. The stems then in use were certainly coarse, ill-fashioned things; yet stems after the modern fashion had been the cause of much mischief. He mentioned a typical case, in which a young married lady, vainly sighing over her unfruitfulness, was treated by a stem. Gradually increasing pain, with nausea and rapid loss of flesh, followed. Only tardy and somewhat incomplete recovery took place after cessation of the treatment. Practitioners forward in advocating treatment of this kind never seemed aware of disasters of the above sort, and not one of the deaths before mentioned had been recorded. Congenital uterine deviations invariably defied mechanical treatment, but no one could diagnose between congenital and acquired. Examination for displacement should be made with a single finger, the patient standing, and those chiefly counted important which caused partial inversion of the vagina.

Dr. MATTHEWS DUNCAN was not prepared to make any lengthened statement of his views, as he would have wished to do, but he would not let the opportunity pass in absolute silence. The paper and speeches in support of it were of great value, but he agreed with neither the substance nor the tenor of them. It was advantageous to consider displacement without descent, and he would confine his remarks to this limited subject. Displacement without descent was, so far at least, an uncomplicated affection. Descent, in addition to displacement, introduced no new kind of disease, but a changed set of conditions not so simple as those of displacement without descent. Now he regarded the morbid importance of displacement as being much exaggerated. It would be nearer the truth to say it had little or no importance. Then the wide range of symptoms attributed to displacement he considered quite unjustified by clinical facts. The treatment of displacement without descent, whether it was desirable or not, was an utter failure; and displacement was never cured, in the sense that the uterus afterwards remained in place, without a pessary.

Mr. THORNTON thought that if uterine cases could always be treated under such favourable conditions as those related in the paper, the results would be as good without the use of either special posture or special pessaries. He agreed with Dr. Duncan in distinguishing displacements without descent from those with it, and in believing that the latter cases alone gave trouble or required aid. He did not believe that stem pessaries ever really cured, but that they often did incalculable mischief. He had some years ago a fatal case from the use of one of Meadows' stems, though every care was taken in preparing the uterus for its introduction, and it was only in 24 hours.

Dr. CORY had this year a case similar to that mentioned by Dr. Thornton. A stem was introduced with every precaution for the treatment of anteflexion in a patient æt. 22, and removed after 24 hours on account of pain. The patient died from peritonitis 96 hours after its removal.

The PRESIDENT expressed his conviction that Dr. Hewitt's careful and long continued studies of the effects of uterine flexion had done much towards advancing our knowledge of an important class of disease. He was himself more convinced of the importance of flexion than he had been previous to a study of Dr. Hewitt's opinions. But he was very far from granting Dr. Hewitt's contention that flexions were the "fons et origo mali" in all forms of uterine suffering, and formed the key to gynæcology. Against such a theory of uterine disease he respectfully protested as being unscientific and unproved. It seemed to him totally impossible that in anything like the number of serious cases of uterine disease as those tabulated, such affections as endometritis, uterine catarrh, and the like, could have been absent. Those who neglected these conditions deprived themselves of an important aid in treatment. He protested against the adoption of a one-idea theory, and pleaded for a Catholic and broad view of the subject.

Dr. GRAILY HEWITT, in reply, said, in reference to the

remarks of the President, that he had not in his work assigned that exclusive importance to flexions which he seemed to imply, but all along insisted on the co-existence of an abnormal condition of the uterine tissues. By using the word mechanical he did not mean that pessaries were necessary in every case. Dr. Gervis had misunderstood him in reference to the amount of rest enforced in the cases related. It was only in patients actually bedridden that such prolonged rest had been required. No doubt the removal of pessaries from time to time was necessary, but he considered that a pessary acted like a splint in case of fracture, and therefore continuity of action was essential. He considered the use of stems a valuable means of treatment, but he felt bound to say that he preferred other methods. He could only understand the failure of the cradle pessary in the hands of others, by supposing that the instruments were not made on his own model. He often found the base of the triangle made too long and the height too little. As to the necessity of using them in retroflexion, he had cured very many cases of severe retroflexion by the combined use of the Hodge pessary, and repeated unbending of the uterus by means of the sound. He was surprised to hear Dr. Duncan's opinion as to the absence of symptoms in case of flexion unless associated with descent of the uterus. His own experience was that descent was almost universally present in cases of flexion, and formed an almost essential part of the disorder.

WEDNESDAY, AUGUST 4, 1880.

WHO IS TO TEST THE GENERAL EDUCATION OF THE STUDENT?

IT has been for a long time, as most of our readers are aware, one of the unheeded "recommendations" of the General Medical Council that the examinations in general education preliminary to ingress to our profession should be dropped by the licensing corporations and entrusted exclusively to Universities; and that the Council is perfectly serious upon this proposition is evidenced by the fact that at the last meeting of the Council, upon the motion of Mr. Simon, a proposal was anxiously debated by it that the whole of the examinations held by licensing corporations should, at one swoop, be refused recognition by the Council. The speech of Mr. Simon, in introducing his motion, and the discussion thereon, illustrate very forcibly the want of knowledge of the existent arrangements, and the want of capacity to provide a practical remedy, which has characterised the Medical Council in many other of its debates. Mr. Simon is anxious that preliminary examination should be altogether independent of medical teaching, and absolutely free from the inducement to the examining body to make easy the access of students to the profession for the sake of catching their fees. So are we; for we fully believe that the general education of medical students will never be what it ought to be until it is tested by an examining board which cares nothing for schools, colleges, or universities. But Mr. Simon, who proposed that Colleges should be forbidden to examine in general education because they are supposed to be interested in passing the student, does not seem to be aware that certain of the Universities, to whom he proposes to transfer the duty of preliminary education are, as teaching bodies, just as much interested in catching the pupils as the Colleges can be. Is it reasonably to be supposed that teaching or licensing institutions will consent to a formal introduction of all the students into a rival teaching or licensing institution just at the moment when their minds and the minds of their parents are on the balance as to where they will study and where qualify? In Ireland, for instance, the two Universities are teaching bodies, and are as anxious as their competitors to attract students, and it would surely be unreasonable to expect the other Irish licensing bodies to hand over to these Universities the opportunity of annexing the student to their own schools. But presuming that an absolutely reliable and independent examining body in general education were available to which the students of every school might be sent without the fear of their being kidnapped, we would venture to join Professor Humphry in his pertinent inquiry as to what the Medical Council knows either to the credit or discredit of the existing preliminary examinations. Mr. Simon has asked it to abolish as insufficient and prejudicial to medical interests a number of examinations which it has never visited and of which it knows nothing but by hearsay, and this at the moment when the Council accepts without question a crowd of trans-pontine examinations, of which it hardly knows even the name. The suggestion was obviously impossible of acceptance, and it was with difficulty permitted to be withdrawn; but the fact that it has been gravely debated shows how little appreciation of what is needed exists in the leading minds of the Council.

There is but one method by which Mr. Simon's object can be obtained and that is the erection of an examination

in general education of sufficient standard and uniform throughout the kingdom, perfectly independent of all licensing bodies and schools, and subject to frequent supervision by the Council itself. No doubt when we achieve conjoint professional examination we shall also achieve this very desirable object, and until then the profession must, we presume, be content that the *pot pourri* of seventy-two examinations, some of which the Medical Council has accepted without a shadow of evidence as to their sufficiency, shall continue to be the educational means of ingress to the profession. Mr. Macnamara's proposal to wipe out these unknown and unknowable examinations from the recognition list must commend itself to everyone, and we content ourselves with the postponement of that proposal only because we are certain that the existing state of things in regard to this and other matters is likely to die a natural death before the General Medical Council could be expected to make up its great mind on the subject.

ENTERIC FEVER IN THE ARMY.—I.

THE Army Medical Department Report for 1878 contains several references to *enteric* fever both at home and abroad; and considering the nature of the discussion now taking place on that subject, we propose to follow it up for a little. In the United Kingdom we are told that the admissions by this disease were at the rate of 1·11 per 1,000 strength, the deaths, too, attacked 205·4; also that while the rate of admissions was higher than in the preceding year, that of deaths was lower. If we endeavour to ascertain what is the precise form of fever designated under this name, we shall be disappointed; that is, whether it is of a specific nature, or idiopathic, with a particular complication, or presenting a particular *condition* of the patient. We find, however, at pages 148 to 160 a series of what are called "sanitary reports." These contain accounts of latrines, sewers, drains, and so on, in connection with barracks and stations; but as far as we can find, not a word as to pythogenic causation of the disease so named; hence, we presume, the term *enteric* is applied in this portion of the Report to a fever of *non-specific origin*. In the portion of the Report having reference to Gibraltar it is stated that the admissions for enteric fever were 18; for simple continued fever 251; and for febricula, 186; also that cases of these diseases occurred in every season, but were more numerous in the latter half of the year than in the first. Still no details are given as to the precise points held by reporting officers as differentiating the forms or conditions of febrile disease severally intended to be thus indicated. The important remark occurs, however, that in two companies of Royal Engineers that arrived at "the Rock" from Papho in Cyprus, cases of paroxymal fevers presented the remittent type, attended by diarrhœa and dysentery. At Malta 920 admissions by febricula, 157 simple continued fever, and 94 by *enteric* fever, with a mortality in the latter of 32—very heavy indeed. Cases occurred in every month except March. More than half the above number were admitted in the months of October and November, but the *type* was less severe during the last three months of the year than during the three immediately preceding them. According to the Blue Book "the cause of the outbreak does not seem to have been clearly ascertained." There is no doubt that the search for specific causes of a disease looked upon as itself specific, failed to discover them at the same time that the attention, it is natural to believe, was thus withdrawn from *influences*, general and particular, operating upon individual states, habits, and tendencies of the soldiers affected. The reporting medical officer writes: "I have referred to the deaths among the civil population (Malta) and find that those for *typhoid* (synonym for enteric?) fevers furnished a percentage of ·04, whilst among the military it was 1·5. During the year 392 deaths from *enteritis* (?) occurred among the civil population, a significant fact when considered with the number of cases of enteric fever among the troops. "In some cases of this fever," well-marked diphtheritic membranes were observed in the tonsils after death along the course of the intestinal canal, covering, in many instances, the ulcers. (Why then, were not these cases returned as of diphtheria?) Simple continued fever and febricula are said also to have been "unusually prevalent." As to *enteric* fever at Cyprus, some very interesting particulars are given. Thus we learn (page 45) that "the earliest case was recognised only after death, and then doubtfully. The patient was under treatment for debility succeeding an attack of malarial fever, but the prominent symptoms became gradually those of supposed *intermittent* dysentery." It does not appear why this case was looked upon as *supposed*, rather than actual dysentery, more especially as about 30 small ulcers existed in the large intestine. In the next fatal case at Larnaca, "ulcers *typical* of enteric fever were found in the lower part of the ileum." "In the other cases returned as enteric fever the diagnosis was not unequivocal; the nature of the disease was *inferred* from the presence of some of the symptoms deemed pathognomonic of this fever, notably that of eruption of rose-coloured papules (not always present in specific enteric fever, and found also in other forms of fever, and in other diseases than fever), and from the pathological conditions found in the bodies of two men who died, rather than determined from the whole course of illness." As to Canada, we are informed by the Report that "enteric fever caused *one* admission. One occurred by febricula, and these two include all that happened by continued fevers among our troops in the Dominion. At Bermuda "enteric fever caused 9 admissions, and one attack was fatal, the case *being complicated with tuberculosis.*" The insanitary condition of the town of St. George was by the medical officer considered a prominent factor in the causation of this disease. In turning to page 164 of the Report the further statement occurs that "enteric fever is endemic in St. George, and during the past year several cases of diphtheria occurred" in the West India command and one admission by enteric fever, namely, at Trinidad. "It was complicated with pneumonia, and terminated fatally." Would not, then, the term *pulmonic* fever have been the more appropriate in this instance? only that it has not yet been admitted into the official nomenclature of diseases. In the Cape of Good Hope Command, which also includes St. Helena, out of 594 admissions by continued fevers, enteric fever supplied 115, and 31 out of the 34 deaths returned under thi

general heading. This fever is described as a *typho-malarial* fever; no definition appears as to what is exactly intended to be conveyed by the expression beyond its most natural significance, namely, that it represented a low or typhoid condition, occurring in the course of malarial, that is, climatorial fever. In an endeavour to follow the history of this disease among the British troops in that command, the Blue Book informs us that in January, 1878, those in the field during the Galeaka-Gaika war suffered, to some extent, from *diarrhœa;* the affection being attributed to chills, difference between night and day temperature, and to the streams from which drinking water was obtained, being more or less impure. Later on in the same month it is stated that "several cases of enteric fever now occurred at Quintana. The medical officer, a civilian, *supposed* the disease to have originated *either* from the polluted state of the air, *or* contamination of the water by carcases of Kafirs, and cattle left unburied since a late action." At the same time, we read, page 243, that a great increase of sickness occurred in the force, due principally to diarrhœa, dysentery, and fever, generally of the continued type, caused, *probably*, by exposure to the sun, and exceptional heat arising from the absence of the usual thunderstorms that occur at this season (that is, to meteorological conditions), by fatigue consequent upon long and arduous marches under such circumstances. This form of fever was also prevalent in King Williamstown, and at the Sheep Wash; the lower part of the the town was in a wretched state of sanitation, and infection was traced from a certain pool close to the camp, although good water was daily brought for their use from the Buffalo river, and they were warned of the consequences. Among the colonial troops it also increased; they had to bivouac night after night in the Pirie bush, their rations were bad, little care was bestowed upon the men, their physique thus lowered by privations and hardships (p. 246). Then we read of further increase of sickness among the troops, regular and irregular; diarrhœa, dysentery, and *enteric* fever the chief diseases; their causes, exposure to damp and cold at night, want of waterproof sheets, the continuance of great draught, and lateness in occurrence of rains (*i.e.*, to general conditions.) At page 255 we read that "undoubtedly the most serious disease that occurred during the late war was this continued fever, designated variously as enteric, malarious enteric, and typhoid malarial. From reports received from three medical officers who were at different stations *many* miles apart, it appears in the first instance to have been imported into the ranks from outside sources (and yet, as we have seen, local meteorological and individual conditions capable of inducing it were enumerated.) As to the *peculiarities* of this fever, one medical officer (p. 255), enumerates the frequent presence of dusky discolouration of the skin (a condition found in fevers generally), the frequency of coma and stupor, with suffused eyes and countenance (the latter are not among the usual symptoms of specific enteric), the presence *of rashes other* than rose-coloured lenticular spots, the *frequent absence* of diarrhœa, or of pain or gurgling over the cæcum (in fact, of phenomena different from those of *typical* enteric fever). A second medical officer says: "Most unquestionably in this epidemic the absence of the usual rose-coloured lenticular spots on the abdomen, of gurgling in the iliac fossa on pressure, and in diarrhœa, was in no period of the disease sufficient, even when combined, to negative the diagnosis of enteric fever. On the contrary, surely it was so, in so far as the specific disease so named is concerned. At the same time, does not the remark indicate a desire to refer the prevailing disease to one particular set of influences, instead of such as are general and necessarily incidental to a campaign? In many instances (p. 256) the symptoms on admission pointed to pneumonia; congestion of the lungs was present in almost every case; in not a few the men complained of sore throat. All very natural, after bivouacking, fatigue and exposure; but why give to the illness another name than is here indicated, namely, pneumonia? In effect, to a case of fever with *pulmonic* complication the term *enteric* is applied! Following this, however, is the remark (p. 256) that "the manner in which diseases of malarial origin led up to the recent outbreak of enteric fever adds considerable weight to the opinion rapidly gaining ground *that this epidemic is something more than* enteric fever; that it is, in fact, a typho-malarial or true *pythogenic* fever, with *malaria* superadded." The post-mortem appearances enumerated (p. 256) were "peculiar patches of congestion in the stomach, and more continuous congestion of the duodenum," in "addition to the usual lesions of enteric." In Mauritius three admissions were recorded by enteric fever, two of the cases fatal; the origin of the disease obscure in all instances, nor could they be attributed to any sanitary defect. In Ceylon, of four admissions under this head, two occurred at Galle, of which, one fatal, and two at Columbo; at neither station could the disease be traced to any sanitary defect. At Hong Kong, two cases, one of which fatal.

THE FEVER IN THE WEST OF IRELAND.

We have not, as may have been observed, concerned the *Medical Press and Circular* as to the controversy respecting the alleged existence of famine fever in the west of Ireland, because we perceived that the dispute was a purely political one, and that the existence of famine fever was as much a part of the parliamentary programme of one party as its denial was necessary to the policy of the other. We think it right, however, to notice the able Report of Dr. Nixon, who was sent down by Government to inspect the fever district, because it puts in commendably plain language the real facts as to the sanitary state of a great part of Ireland. Here is his description of what he saw:—

In most of the cabins cattle and pigs are kept in the room that is occupied. The sewage matter is partly carried off by an open drain which runs through the centre of the floor, whilst stagnant pools containing all sorts of offensive matter lie in front of the cabins. In this village there is no sewerage of any kind, and no road for car within more than a mile's reach. The food of the people here consists almost exclusively of Indian meal without milk.

I had the honour of forwarding Dr. Burke's report to you in my last letter. I visited with him a patient, æt. 20, living in Collaghagh, 2½ miles from Foxford. This patient had been ill of typhus fever for some seven or eight days, and had not sent for medical relief. Two of his brothers had passed through the disease recently, one in Swineford

Fever Hospital, the other at home. The family consists of six members, and no precautions whatever were taken to prevent the spread of the fever. The cabin in which these people live is situated high up on a mountain side, and only accessible by crossing a wide stream and walking through an extensive bog. There is no road leading to the place. I mention these particulars to show the difficulties which exist in dealing with such cases. No ambulance could be brought here, the patient was too ill to be carried to the nearest road; and, moreover, no assistance of *any kind* was sought for. Nothing would be known of this case but for the fact of his brother having had fever at home.

On to-day I proceeded to inspect the cases of illness reported in Swineford and Kilkelly dispensary districts. . . . In a third house I saw a patient suffering from typhoid fever with serious disease of the lungs. Nothing could exceed the complete absence of sanitary arrangements in this village. There were fully eight inches of manure in one cabin, in the room where seven persons lived, and the woman of the house explained that she could not clean it out, as then she would have no manure. A large pond, filled with greenish water, and containing all kinds of sewage matter, was in front of the house, and the sewer in connection with it had its mouth closed by a large stone put against it. Yet, although illness existed in three families in this village for over two months, it was only on the preceding day that the medical officer of the district was sent for.

I consider that in these cases the disease was induced by the prolonged use of improper food, Indian meal without milk or flour, and defective sanitary arrangements. In Ballintadder five members of a family had been ill for some weeks, and at the time of my visit three were still confined to bed from typhoid fever. The cabin in which these persons lived was extremely offensive, and on entering it the smell from the excessive amount of organic matter in the air was almost overpowering. In the small single-roomed cabin in which the three patients, the mother and two children lived, I counted at the time of my visit three cows, a number of chickens, three cats, and a large dog. The food of these people was meagre, and consisted almost entirely of Indian meal; yet they had 13 or 14 acres of land. In an adjoining house three boys were lying, one of them since June 1st. Two of the patients were suffering from typhoid fever, one from dysentery. The water used for drinking purposes by both families was taken from a well in a neighbouring field. On examining the well I found it was merely a pit, which was enclosed by a stone wall, and into which opened the drains from the field, and, in wet weather, the washings of the roadway. The field had been manured during the winter with guano. The well had been cleaned about a month previously, when a quantity of slimy foul-smelling matter was removed from its bottom. The water looked dark and muddy, and it had a greasy scum upon the surface.

I have already, in a former report, referred to some of the cases of fever which occurred in the town; nearly all those cases, and many in other districts, owe their origin to a woman who died of typhus fever, and in whose house a wake was held. So many facts have come to my knowledge respecting the relation of this case to the epidemic in certain districts, that I cannot too strongly urge the necessity of early isolation and removal to hospital in cases supposed to be typhus. I have no doubt but that insufficiency of food, or food of an unvarying nature, strongly predisposes to the spread of every infectious disease. The habit of using food cooked always in the one way leads to a quantity being taken only sufficicient to appease hunger, not to maintain nutrition or impart strength; again, the mental distress which privation engenders must also tend in the same direction, as one of the agents which lessen the resistance power of the individual to infection; so also disregard of sanitary precautions, I believe these conditions capable of converting a disease ordinarily endemic into an epidemic. But I consider it is mainly to contagion and overcrowding that we must look for the immediate exciting cause of the spread of typhus fever, or of its generation *de novo;* hence, the special indications for its prevention. Very great difficulties exist in this union in meeting these indications. The effect of overcrowding can only be palliated by regular sanitary inspections of the cabins in the different districts of the union. There is some unreasonable unwillingness on the part of the patients, or of their frends, to seek admission to the fever hospital, notwithstanding the arrangements made for their reception, and treatment there. I have no hesitation in suggesting that the provision in the Public Health (Ireland) Act relating to the removal of infected persons to hospital by order of a justice should be rigidly enforced.

In presence of such a state of things as that which Dr. Nixon divulges to Parliament, but which most workers in the Irish poor-law knew all about long since, it is proper to ask why the population of these districts are allowed to live like unclean beasts, and to spread to their neighbours the diseases propagated by their noisome mode of life. Has there been no attempt made by the rulers of these people to raise them from the misery and degradation of this life to respectability, cleanliness and health? Yes, there has; a Public Health Act which provides a remedy for all this, has existed in Ireland since 1866, was re-enacted and improved in 1874, and made compulsory, and in 1878 was again re-constructed and re-affirmed. If, then, the legal powers, the money and the means exist for changing the state of abomination which Dr. Nixon unfolds into a better condition of things, some one must be to blame that these means are not put in action. Who? The Irish Local Government Board itself, the Public Department which sent down Dr. Nixon to see and make known to Parliament the fatality which has resulted, and which results every year from the policy of the Board itself.

How has this Board administered the sanitary law entrusted to it? We assert, without hesitation, and we appeal for proof to the pages of this journal within the last five years, that the Irish Local Government Board has done everything in its power to obstruct the progress of sanitary reform in Ireland. It has encouraged with warmth the disposition which needed no encouragement of the Boards of Guardians throughout Ireland to turn their backs upon every effort in favour of cleanliness, and it has steadily resisted the entreaties of sanitarians and the medical profession, and has turned a deaf ear to the representations of those who told them the same story as that which Dr. Nixon tells now. Will anyone in Parliament ask Mr. Forster, who is the President of the Local Government Board, to state what that Board has ever done to induce activity in Irish sanitary authorities, and whether they have not only tolerated, but encouraged the making of the public health organisation the disgraceful sham which it undoubtedly is?

Notes on Current Topics.

Special Hospitals.

At the recent distribution of prizes to students of the Dental Hospital of London, Mr. Sibley, the chairman, in his address referred at length to the subject of the education of dentists and other specialists, and among his remarks the following upon special hospitals are worth quoting as the opinion of a highly representative member of the profession. We have no doubt that Mr. Sibley's views on this subject are shared by the vast majority of the profession, and we think thanks are due to those who, like Mr. Sibley, avail themselves of the opportunity of expressing their opinion:—

Little apology is needed to justify the existence of

this special hospital (the Dental Hospital). Almost, but perhaps not quite in the same category, stand the Ophthalmic Institutions. To a great extent the objects of these might be as well performed in a department of a general hospital, but the good work done at these institutions justifies their existence.

For obvious reasons mental affections and lying-in cases require separate establishments. So also consumption is, unhappily, so common and so extensively spread a disease, that it would be impossible to take such cases into a general hospital. They would fill and overflow all the available beds to the exclusion of other cases. It is, therefore, necessary to have separate institutions in which such patients can be properly cared for.

Small-pox and fever cases require isolation, and therefore must be treated in separate institutions. Children's diseases have some claim to separate management, but most of these cases can be cared for in a children's ward of a large hospital.

This short catalogue includes almost all necessary establishments. The multiplication of special institutions is not calculated to confer proportionate benefits upon the poor. The expenses of management, as a rule, are out of fair relation to the amount of good done, and the affairs of these smaller institutions are not sufficiently looked into by responsible and independent managers.

Another very great evil resulting from this system of multiplication of special hospitals is that medical education is seriously interfered with. The young medical men sent out into the world from the great hospitals, have their opportunities of studying various special forms of disease sadly curtailed, and the result must be that the public will be supplied with doctors who have not had sufficient opportunities of studying special but common forms of disease. This may be of little moment to the public living in the great centres of population where specialists are numerous, but it is of importance to any one who may happen to be in a more remote district, or in distant parts of the world. These evils would be to a great extent remedied by the establishment of more special departments at the general hospitals, affording the opportunities of studying and treating various specialities to the fullest extent, but controlling the conduct of these departments by the general principles which govern the parent institution.

The Naval Medical Service.

The *United Service Gazette* of 24th July has an article on the Naval Medical Service, with which we, to a great extent, agree. Like our contemporary, we trust that to such medical officers as may be compulsorily retired, a sufficiently liberal scale of pension will be granted to deprive them when in private life of all just grounds of grievance against "the authorities," for as experience has amply shown, the grumblings and complainings of men who have been, or imagine themselves to have been, badly treated, exert a most evil influence upon all with whom they come in contact, and induces a spirit of discontent among the juniors. But, on the other hand, may we not with propriety express our opinion that the system of clearing away the seniors in order to give promotion to the juniors "has increased, is increasing, and ought to be diminished?" This system is by no means limited to the medical service, but extends, or is about to extend, to all branches, so that the tax-payer has the prospect at no distant date of having to support a larger non-effective than effective list of officers of all kinds and grades, while, at the same time, a number of junior officers in experience and age are paid for performing the very duties that the seniors and more experienced are also paid, on the retired list, for *not* performing. As in the army, so in the navy it is fair and reasonable that old officers should have the the option of retiring on such pensions as they have earned by long and faithful service; but we doubt the propriety, alike in the interests of the public as of individuals, of drawing a hard and fast line, by which let, a man be in good or ill-health, fit or unfit, willing or unwilling to serve, he shall, on attaining a particular age, be shelved. With regard to medical officers the question has an important bearing upon the management and treatment of our troops and sailors abroad; nor will the looked-for *run* of promotion among themselves be more than very temporary, for as a necessity, after the clearance authorised by warrants have taken place, the block in promotion will take place farther down the several lists, and men get tripped up by the age clauses before they shall have attained administrative rank.

Can it be True?

In a late number of this journal we alluded to certain occurrences said to have taken place on board H.M.S. *Newcastle*. On that occasion we wrote hesitatingly regarding them, for the reason that so very unusual were they in their nature that we looked for further particulars than we were then in possession of, to enable us to take the subject up as we should have wished. Such particulars have, however, not yet reached us, so that as the matter stands at present time we can only look upon it in the light of a personal rather than public grievance. No doubt it is quite possible to so stretch regulations as to render their action extremely unpleasant, but then a medical officer, like any other officer, has it in his power to represent to his superiors any grievance under which he considers himself to labour; and as a rule—certainly by no means without exception, but still *as a rule*—he is sure to have justice done to him. The instance we refer to is clearly one for representation to the Director-General of the Navy Medical Department, and by him, should he report it, to the Lords of the Admiralty.

Since we first drew attention to this subject several of our contemporaries have alluded to the circumstances. It appears to us that the episode on board the *Newcastle* involves the questions of the existence or otherwise of preventible causes of sickness; that of the medical officers in charge to discover those causes; and that of discipline as between the officer commanding that ship and certain officers serving under his command. The "quarrel" is no doubt a "very pretty" one as it stands, and we shall probably hear more about it by and bye.

Salicylate of Soda in Petechial Typhus.

According to Dr. Gregorianz (*La Presse Médicale Belge*), the effect of this salt is very favourable; it lessens the tendency to delirium, lowers the temperature, and prevents renal complications. The progress of the disease also is influenced—it developes more rapidly, and convalescence is hastened. An inconvenience is its depressing effect on the heart, but this may be obviated by giving it in small doses (5 grammes), and adding a stimulant, such as sherry or brandy, to the mixture.

Anæsthesia during Sleep.

A most important papar was read by Dr. Quimby at the recent meeting of the American Medical Association, which seems to have settled the question whether a sleeping individual could be brought under the action of chloroform without being awakened. His attention had been drawn to the subject by a case which occurred in Jersey city, in which a woman was accused of participating in the murder of her husband as she was in bed with him when this was perpetrated. She held that she had been chloroformed during her sleep, but it was contended that this was impossible, as the fumes of chloroform would have awakened her from a natural sleep. Dr. Quimby was examined as an expert; but he declared that he had never administered chloroform during sleep, and that the books were silent on this point. Since then he has made three experiments—one upon a gentleman, who, by means of three drachms of Squibb's chloroform, he transferred from natural to artificial sleep in seven minutes without awakening him. In the two other cases he performed minor operations upon boys, having chloroformed them when asleep. He concludes—(1) that minor surgical operations may thus be done with perfect safety and much more agreeably than in the ordinary way; and (2) that an individual somewhat skilled in the use of chloroform might enter a sleeping apartment and administer chloroform with evil intentions to a person while asleep.

Superannuation—The Medical Officer of the Crossgar Dispensary.

Mr. Meldon, M.P., asked the Chief Secretary last week if it is the case that the medical officer of the Crossgar Dispensary District in the union of Banbridge, having after forty years' service applied for superannuation on the ground of broken-down health, a meeting of the guardians has been summoned to consider such application, and to pass a resolution "to record on the minutes their approval of the manner in which the medical officer has filled such office for a period of forty years, but that the guardians cannot add to the rates by granting any retiring allowance." And, if the Government will promote or support a measure to make the superannuation of Poor-law medical officers, in proper cases compulsory on boards of guardians?—Mr. Forster pointed out that the resolution had not yet been passed, and therefore the question was somewhat premature. He would defer any answer for the present.

The case alluded to by Mr. Meldon is that of Dr. Davison, and the attitude of the board of guardians towards him may be judged from the fact that one of the roughs of that conclave—on the application for a pension being read—insulted Dr. Davison by inquiring whether "he wanted out-door relief."

At a meeting of the General Committee of the International Medical Congress, recently held at the College of Physicians, Dr. West proposed that ladies should be admitted as members of the Congress. Mr. Gant seconded the resolution, and at the division nineteen voted in favour of and twenty-six against.

The Treatment of Diphtheria.

Dr. George Hill, of Hughesville, Pa., strongly advocates the following treatment of this disease in the *Med. and Surg. Reporter*. As a mixture, he prescribes in varying strength of dose, according to the age of the patient, aquæ chlorinii., sodii sulpho-carbolat., glycerinæ, of which two examples will suffice:—

℞ Aquæ chlorinii, ℥v.;
Sodii sulpho-carbolat, gr. xv.;
Glycerinæ, ℥iss.;
Aquæ, ad. ℥ij.;
M.

℥j. every two hours, for a child æt. 10 months:—

℞ Aquæ chlorinii, ℥iij.;
Sodii sulpho-carbolat., grs. clx.;
Glycerinæ, ℥j.;
Aquæ, ad. ℥vj.
M.

℥iij drachms every two hours—to be held a moment before swallowing—for a girl æt. 18.

In combination with this form of mixture he gives sulphur sublimatum, in fifteen-to twenty-grain doses every six hours to adults, until an apparent effect is produced. Locally, purely pulverised tannic acid is applied to the exudation growth with a moistened swab, every four hours, and as a gargle—

℞ Sulphurated sol. sodium chloridi, ℥j.;
Glycerinæ, ℥j.;
Aquæ, ℥iij. M.

Or, glycerate of tannic acid, ℥j. glycerate of carbolic acid, ℥ij., mixed and reduced one fourth with water, and applied every four hours.

Where the disease extends into the trachea he strongly urges the use of lime steaming, for which purpose an ounce and a half of quicklime, fresh from the kiln (not air slaked), is put into a tin cup, and covered with a pint and a-half of cold water. Over this is inverted a funnel, not so closely as to exclude the air. To the top of the funnel is attached a tube with a suitable mouth-piece. The rising steam is to be inhaled for half an hour; if the steam fail, to be quickly renewed. An intermission of half an hour is allowed, and then the steaming to be resumed as before, and so on day and night with the utmost perservance. Emetics of syrup of ipecac. occasionally required to expel detached fragments, and averting the impending suffocation that necessarily tends to occur in such cases. Ice to be allowed freely. Whisky to be avoided, only where there are strongly marked symptoms of failing vitality. The patient must be carefully watched and treated during convalescence, and should be seen at least once a week until a normal state of the throat has been fully established. Dr. Hill condemns tincture of iron, tincture of iodine, and nitrate of silver applications to the throat. Under this treatment Dr. Hill has not lost a diphtheritic case for a period of five years, the same successful result being experienced by Dr. G. A. Hill in his practice whilst carrying out the above line of treatment. The cases published in support were typical in their nature, and most interesting in the record of their progress towards recovery.

Dr. Matthews Duncan has accepted the invitation of the Council to deliver the Inaugural Address of the Midland Medical Society for the ensuing session.

Sewage.

On Monday, July 26th, a large number of gentlemen interested in the treatment of sewage accepted the invitation of the chairman of the Native Guano Company, Limited, to inspect their works at Aylesbury, a special train conveying them to the scene of operation. The various processes whereby the thick murky stream from the Aylesbury town sewer was deprived of its injurious elements, and the effluent stream transformed to an innocuous and almost pure water, were viewed and explained in succession by the officials present. The process is that known as the A B C; the inflowing current circulates through a series of tanks in which the solid constituents are deposited, their separation being aided by the addition of a precipitant, and with such completeness that the excrement water is clear, odourless and tasteless, the perfectly healthy nature of which is testified by the presence of a large quantity of agile fish in a pond supplied by it. The deposit in the tanks is submitted to treatment, drying, pressure, and admixture with animal charcoal, &c., whereby it is made of great value for manuring purposes. The daily average flow of liquid through the tanks is about three hundred thousand gallons, and the weekly output of "native guano" from ten to fifteen tons, for which a ready sale is always obtained. Though the day chosen for the demonstration was eminently unfavourable, being very wet, unanimous approval was expressed, and much surprise at the simplicity and excellence of the arrangements. At the lunch which followed the inspection, the sewage question was considered in a series of speeches by the Chairman, the Hon. W. F. B. Massey-Mainwaring, Colonel Siller, Mr. Clare Sewell Read, Captain Bedford Pim, R.N., and others.

The Guy's Hospital Scandal.

The fact that a jury has found a nurse at Guy's Hospital guilty of the crime of manslaughter will create little surprise in the minds of those who have feared the evil consequences likely to follow from the changed system introduced by the reforming school. All along during the dispute we have pointed out the possibility of some such result as has been published in the recent proceedings; and being the first of the weekly medical papers to insist on the dangers to be apprehended, we likewise feel that an early attention to the measures we recommended would have prevented the sad realisation of our forebodings the past week has witnessed. That the verdict pronounced against Nurse Ingle will have the effect of settling matters in a way conformable to the frequently uttered opinions of the medical staff can hardly be doubted, but our regret will be universally shared that the end should have been brought about in a manner likely to bring extensive discredit to a great institution. In connection with this subject it will be well to recall the uncompromising expressions of members of the staff of Guy's who have repelled the charges brought against the former management of the charity, by the self-elected champion of the new *regimé*. It was scarcely politic for this young scribe to re-enter the lists when she had already been previously routed; and we would hope the severe discomfiture she has again experienced will tend to convince her of the folly of persisting in defence of a system emphatically condemned by those whose experience and position lent authority to their words.

The Parkes' Museum of Hygiene.

The Lord Mayor presided at the Mansion House, on the 27th ult., over the first annual meeting in connection with the Parkes' Museum. The report announces that since January 1st over 2,000 visitors have been registered, and that the winter demonstrations to artisans and others were largely attended, evidence being also forthcoming that these had been attended with benefit to the hearers. The committee appeal for subscriptions to enable them to carry out the aim in view by its originators, and they urge as a first necessity "the establishment of the museum in a position more independent and more accessible than that which it at present occupies." Sir Wm. Jenner, Sir Joseph Fayrer, Mr. Edwin Chadwick, C.B., Professor Erasmus Wilson, and others, were present at and participated in the proceedings.

Illness of the Premier.

After leaving the House of Commons on Friday last, Mr. Gladstone got a severe chill, the symptoms assuming a somewhat grave character, the following day he was unable to attend the Cabinet Council, and Dr. Andrew Clark was immediately sent for, who, finding his distinguished patient in a severely feverish state, deemed it prudent to remain with him through the night. On Sunday morning Dr. Clark issued a bulletin to the effect that the Premier was suffering from exhaustion, with congestion of the base of the left lung, and fever. During Sunday the case was considered critical, and her Majesty and the Prince of Wales were constant in their inquiries by telegraph and otherwise. Absolute repose, however was strictly enjoined by Dr. Clark, and no one beyond the members of the patient's own family were allowed to see him. At the time of our going to press the fever had subsided, and the danger passed; but much care will be required to prevent a recurrence of the local symptoms.

Arsenic in Chorea.

According to *Bouchardat's Ann.* we find that, from observations made in the service of M. Siredey, by M. Pomel, upon the treatment of chorea, the following deductions are made:—

1st. Of all the remedies employed in chorea, those which are the most rapid and sure are the arsenical preparations; particularly arsenious acid, which at once produces rapid amelioration of the symptoms, and brings about a speedy cure.

2nd. Grave cases of chorea that have resisted other treatment yield, frequently with promptness, to arsenic.

3rd. To obtain the full benefit of the arsenical treatment, it is necessary to administer the medicine in such doses as to produce, as speedily as possible, the constitutional effects or signs of arsenical saturation.

4th. Even in children affected with chorea, no hesitation should be felt in giving strong doses of arsenic, in order to reach the point of saturation quickly.

5th. Without denying the possibility of danger in the use of arsenic in the treatment of chorea, yet no case has thus far been recorded to establish the fact.

Benzoate of Soda in Gonorrhœal Ophthalmia.

Lyon Med. tells us that Dr. Dor, who for the last two years has used the benzoate of soda with great success in the purulent ophthalmia of infants, has recently had the opportunity of treating a well-marked case of gonorrhœal ophthalmia, recovery taking place in a few days, without any opacity being left. He kept iced compresses constantly to the eye. The benzoate of soda was employed in a 20 per cent. solution, and tannin in a 10 per cent. solution, ten drops being instilled every three minutes. All secretion which issued from the eye was removed by means of a wash consisting of 100 per cent. solution of benzoate.

Pilocarpine in Uræmic Convulsions.

LEVEN (*La Presse Medicale Belge*) advocates the use of subcutaneous injections of pilocarpine in uræmic convulsions. A young girl, affected with albuminuria, was seized with convulsions with complete anuria. Two injections of hydrochlorate of pilocarpine had no effect, but at the third the remedy produced its ordinary effect. The patient, who was comatose, gradually came to herself, at the same time profuse perspiration and abundant salivation were produced. After a fourth injection the convulsions ceased and the patient recovered. The temperature oscillated between 37° and 38° C. The saliva contained 10 per cent. of albumen.

Professor Spence, of Edinburgh.

A MOVEMENT has been set on foot to present Professor Spence with his portrait, and to offer a copy of it to the Edinburgh College of Surgeons for hanging in their hall. There is a universal feeling that Professor Spence's services to scientific surgery have given him a prominent claim to professional recognition and gratitude. It is hoped that the number of guinea subscriptions will be such as to enable the committee to give each subscriber an engraved copy of the work.

Eucalyptus Spray in Pharyngeal Diphtheria.

DR. MESTER (*Berlin Klin. Wochen.*) employs from six to sixty drops of the following solution for each spray inhalation:—Essential oil of eucalyptus leaves, 5 grammes; rectified spirits of wine, 25 grammes; water, 170 grammes. Previous to inhalation the mixture should be shaken. Where the inhalation has to be repeated hourly, the solution must be diluted. The odour being agreeable, does not cause headache, in this respect being superior to turpentine or carbolic acid.

Transposition of the Viscera.

A CASE of complete transposition of viscera was recently observed in a young girl, æt. 17, who died under the care of Dr. Dumont at the Hotel Dieu at Caen. At the autopsy all the viscera, both thoracic and abdominal, though perfectly normal in form and structure, were completely transposed, those usually on the right being on the left side and *vice versâ*. Their relative positions however were perfectly maintained, so that there was no interference with the functions.

The Harvey Statue.

THE full-sized clay model of the statue of Harvey, which is to be erected at Folkestone, has nearly approached completion, and the sculptor, Mr. Joy, invites the subscribers to the Tercentenary Memorial Fund to a private view of the model (upon presentation of address cards), on Wednesday, August 4, from eleven to half-past five, at his studio, 8 The Avenue, 76 Fulham Road, S.W.

Dangers from Hydrophobic Patients.

BY inoculation of rabbits with the saliva of a hydrophobic patient, M. Raynaud has found that the rabbit took the disease in five days. Two other rabbits inoculated with hydrophobic saliva also became hydrophobic. The conclusion drawn is that the saliva of hydrophobic patients is virulent, and that this fact merits more attention than is now generally given to it.

The Select Committee on Contagious Diseases.

THE Select Committee of the House of Commons appointed to inquire into the operation of the Contagious Diseases Acts held a private sitting on Monday week, when it was decided that the examination of witnesses should not be proceeded with during the present session. The Committee will not meet again before the prorogation of Parliament.

Dr. Tanner's Fast.

DR. TANNER'S continues in his determination to complete the forty days' abstinence from food to which he has pledged himself. The condition of the experimentalist is one varying between excitability and depression, and the latest reports indicate that he may successfully complete his self-imposed task. The result will be—what?

LIVERPOOL has accomplished in a few weeks the self-imposed task of raising £80,000 to endow a university college for the town. This result reflects the highest honour upon the energy and liberality of its citizens.

DR. DIXON has been presented by the nurses of the Newcastle-on-Tyne Infirmary with an elegant silver-mounted decanter, as a mark of esteem, on his resignation of the senior house surgeoncy of the institution.

A COMPLETE list of the Army Medical Service to be sent out to Afganistan is not yet published, but amongst those who go by the first ship, the *Orontes*, to-day, are:—Surgeon-Major Mansell and Surgeons Corven and Clark, besides four members of the Army Hospital Corps.

THE *Philadelphia Reporter* says that there are over 700 drug stores in Philadelphia, and not one of these could exist on its legitimate business of compounding prescriptions. The superfluity is due to the profits of patent medicines and counter-prescribing.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Nottingham 14, Plymouth 14, Newcastle-upon-Tyne 14, Hull 16, Bradford 17, Brighton 18, Portsmouth 18, Bristol 18,

Birmingham 19, Manchester 19, Edinburgh 20, Sheffield 20, Leeds 21, London 21, Oldham 22, Norwich 22, Glasgow 23, Salford 23, Sunderland 23, Leicester 24, Wolverhampton 25, Liverpool 26, Dublin 30.

THE death-rate last week from the seven principal zymotic diseases per 1,000 in the large towns ranged from 0·7 in Plymouth, to 7·0, 7·3, and 7·6 in Dublin, Brighton, and Leicester. Scarlet fever show the largest proportional fatality in Sheffield, Norwich, Salford, Dublin, and Bradford; and measles in Leicester. Small-pox caused 3 more deaths in London, 9 in Dublin, but not one in any of the other other large towns. The deaths referred to diarrhœa, which had steadily increased in the five preceding weeks rose still higher last week; the mortality from this disease showed the largest excess in Brighton, Leicester, and Salford.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE FINANCIAL DIFFICULTIES AT THE UNIVERSITY OF ST. ANDREWS.—Notwithstanding the brisk trade carried on in the sale of degrees by the University of St. Andrews and the gifts of the notorious Dr. Beaney of Antipodean celebrity, this ancient seat of learning is at present in serious financial embarrassment. Considering the gravity of the situation, it is certainly to the credit of the professors that so little has been heard regarding it. We understand that, speaking generally, not less than a third, and in some cases nearly two-thirds of their previously very modest incomes have this year disappeared. Nor is there any probability, when we take into account the permanent reduction in the value of the lands from which they derive their incomes, of this state of matters being improved. Under these circumstances the Home Secretary was questioned on the matter by Sir Trevor Lawrence. Sir William Harcourt said that the Government would consider the matter during the Parliamentary recess, and would state early next session any proposal they had to make regarding St. Andrews. It is to be hoped that the Government will make a suitable provision in the forthcoming estimates.

THE UNIVERSITY OF GLASGOW.—The ceremony of capping the graduates in Medicine, Law, and Arts, took place in the Lower Hall of the University, on the 29th ult. The Very Reverend Principal Caird presided, and there was a considerable attendance of the public to witness the ceremony. Professor Robertson presented the graduates in law, and Professor Gairdner presented the graduates in medicine. Seventy-nine received the degree of M.B. and C.M., and nine the degree of M.D. After the ceremony of capping Professor Cleland delivered an address, the subject of which was "Truth, Pathology, and the Public." In the course of his address Dr. Cleland said that "it is palpable that in all professional education there is a large mass of fact to be learned, but obvious also that the facts will be of little use without the art of handling them and turning them to account. More especially is this the case in medicine. I do not doubt that you have all learned a great number of details of treatment which you will use to the advantage of patients yet unborn, as well as others, it is to be hoped. But remember the changes which take place in treatment are perpetual, and that there is nothing reliable in any treatment which is not based on science. This lotion and that operation, O young surgeons; this plaister and that panacea, most promising physicians, will be superseded, it may be, in a very few years; but if you have learned the scientific method you will help, by patient and accurate observation and thought, progress which shall endure when much crude innovation known by the name shall have been abandoned and forgotten. The physician is set face to face with nature; and all correct treatment of disease must be founded on an accurate knowledge of pathological changes. If your practice be not so founded, it will be quackery; and the public and the State are to blame that the opportunities of arriving at a correct pathology are not what they ought to be. There are two senses in which pathological anatomy is the foundation of correct practice. In the first place, the profession, as a profession, could have no knowledge at all of any pathological change without studying morbid conditions after death. That is to you self-evident; but the general public have never caught hold of the idea properly, or they would take more care that the greatest possible facilities should be given for the prosecution of inquiries on which their own health ultimately depends. But let the public listen to this further statement, which you will all recognise as true, though some of you will forget it as time rolls on—that the practice of each individual practitioner is trustworthy only when he makes use of frequent opportunities of examining after death to verify and supplement his judgments where they have been right, to test his guesses and suppositions that he may see how far they have accorded with fact, and most of all to correct the numerous errors into which the wisest and the most experienced continually fall."

REGISTRAR-GENERAL'S REPORTS.—According to the weekly return of births, deaths, and marriages for the eight principal towns of Scotland, the death-rate for the week ending with Saturday, the 24th July, 1880, was 20·6 per 1,000 of the estimated population. This rate is 3·2 above that for the corresponding week of the last year, and 2·0 above that for the previous week of the present year. The lowest mortality was recorded in Aberdeen, viz., 11·6 per 1,000, and the highest in Leith, viz., 29·7 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·3 per 1,000, almost the same as the rate for last week. Acute diseases of the chest caused 69 deaths, or 11 more than the number recorded for the previous week.

GLASGOW ROYAL INFIRMARY.—An announcement appears in the Glasgow newspapers inviting candidates for the offices of physician and surgeon to the Institution in room of Dr. Scott Orr and Dr. Watson, whose term of office expires next month. It has been the rule hitherto to re-appoint physicians and surgeons who *thus retire*, and we think, with the utmost respect for these gentlemen, that a limit should be placed to the term during which hospital appointments can be held. Matters were much better under the old *regimé* at "the Royal."

NORTH OF SCOTLAND MEDICAL ASSOCIATION.—The annual meeting of this Association was held in the Medical Society's Hall, King Street, Aberdeen, on Saturday, the 24th ult. Dr. Mellis, Fraserburgh, was appointed chairman for the ensuing year, and gave a short address in which he urged the importance of students of medicine being trained as skilled general practitioners rather than scientific specialists. Some discussion took place with reference to a proposal to unite with the local branch of the British Medical Association, but no definite resolution was come to. The members afterwards dined

the Palace Hotel, along with the members of the Branch of the British Medical Association.

ABERDEEN UNIVERSITY MEDICAL SUMMER SESSION.—This Session was concluded on the 23rd ult. Certificates of merit distributed to the successful students.

THE WESTERN GENERAL INFIRMARY.—The annual meeting for the distribution of the awards gained by the successful students in clinical medicine and surgery was held last week, at the Western Infirmary. Mr. Thomas Watson, chairman of managers presided, and after a brief address, distributed the following prizes and certificates: Clinical Medicine—Medal, Alexander Adam; honorary certificates (in order of merit) James Kerr Love, C. Fredk. Pollock, W. F. Panmar, Donald Macleod. Clinical Surgery—Medal, John Ritchie; honorary certificates (alphabetical order) Charles Gray, James Kaye, William Morrison, William Patullo, John M. Young.

THE IRISH MEDICAL DIRECTORY FOR 1881.

WE are requested to remind the profession throughout Ireland that the issue of their Directory for 1881 is now in course of compilation, and the Editors earnestly beg for the immediate return of the circular which has been sent to each medical practitioner—*whether or not there be any correction necessary therein*. It is hoped that those gentlemen who have not yet sent back the circular will, by doing so at once, relieve the Editors of the expense and trouble of a second issue, and contribute their quota to the general accuracy of the work.

A NEW LUNG FOR DUBLIN.

WITHIN the past week Lord Ardillam—better known and respected as Sir Arthur Guinness—presented a most beautiful and valuable contribution to the solution of the Dublin sanitary difficulty, in his princely donation of a new free park to the citizens. St. Stephen's Green—now a handsome and health-giving place of recreation for all those who need free breathing space—was for about sixty years the close garden of the nurse-maids and children of the inhabitants of the Square, and it was Lord Ardillam who cut with liberal hands the Gordian knot of legal and personal obstruction to its being declared free to the citizens. In doing so he has earned for himself the honour due to a philanthropist and the gratitude due to a benefactor, and—we may add—has done more towards amending the insalubrity of South City denizens than all that the legal guardians of their health have ever attempted.

REGISTRATION OF BRITISH DEGREES IN CANADA.

THE attempt of the Canadian Medical Council at Ontario to compel all persons who desired to practise in Canada to qualify there has come to an end. They attempted to effect this purpose by imposing a registration fee of four hundred dollars on all persons who sought to register and practise upon a British qualification. Dr. Mallory, a Canadian graduate, who subsequently qualified and registered in England, recently applied to the Council for registration. This was refused, and the doctor issued a process in the Court of Queen's Bench calling upon the Council to show cause why he should not be registered. The case was heard before the Chief Justice, who gave his decision in favour of the plaintiff. The learned judge was severe upon the Council, and warned that body not to attempt to extort a four hundred dollar registration fee from duly registered British graduates who desire to practise in Ontario.

Literature.

THE SURGEONS' POCKET BOOK. (a)

IN MEMORIAM.

SINCE this work appeared its talented author has succumbed to the fatigues and trials incidental to war—stricken down by disease while serving as principal medical officer in charge of the Cabul force. Surgeon-Major Porter was a perfect type of the regimental surgeon. Some of the illustrations in the volume before us bear upon them the number 97, that of the regiment he loved so well, and in which he was so much beloved by all ranks composing it. It was while serving *in* that corps, during the Indian Mutiny, that he obtained much of that experience in the surgery of war and in administration, which his rare capacity enabled him subsequently to turn to such valuable account. We who write this notice first made the acquaintance of Dr. Porter while giving aid to the wounded under fire on the occasion alluded to at page 81 of his "Pocket Book." He there describes the operation in which we were concerned namely, raising a piece of bone that a fragment of exploded shell had depressed upon the brain of a soldier, and he mentions the circumstance that although consciousness was restored for a little while, yet the subject of the wound shortly afterwards died. After death an extensive counter-fracture along the base of the skull was discovered; but the operation we had performed served an important purpose in that it restored sensibility for a little time—quite sufficient, had its subject been an officer, to make arrangements, it may be, regarding his family affairs; and this to our mind showed clearly the propriety of its performance. Like all military surgeons of considerable personal experience, Dr. Porter is opposed to the "feverish practice of bandaging places," and to performing operations at the dressing stations. Volunteer and other fashionable *aides* have in some recent wars done much to foster this very *feverish practice* which he so strongly condemns, for, as he observes, "the rapid firing of recent weapons provides us such a crowd of wounded that ambulances are immediately thronged, and reliable diagnosis between the cases suitable for operation and for conservative surgery is rendered impossible." In fact, under such circumstances, as in others, the difference soon becomes apparent between experience and sensationalism; the one only does what is absolutely necessary, and that quietly and methodically; the latter, able really to do but very little, performs that *little* with as much demonstration as possible, and very much to the inconvenience of individual wounded and to the more steady-going and *collected* of their assistants. Dr. Porter's work before us is so complete that for the army surgeon in war it supplies every information that he can possibly require; but, alas! it shows too how great a loss the public service has sustained in the death of that most estimable of men, and pattern of what his successors in the Army Medical Department should aim at becoming.

Special.

INDIAN ITEMS.

HEALTH OF THE TROOPS IN AFGHANISTAN.—A correspondent of the *Manchester Guardian* describes the suffering of the troops, whether native or European, from the heat and the excessive labour necessitated by the weakness of the various garrisons, and he states that if the occupation is to be prolonged through another winter it will become a very serious question as to how the troops are to be provided. The mortality and invalidings consequent upon the terrible cold of the last winter were very great, and the difficulty in obtaining recruits from India to fill up the gaps thus formed in the fighting line becomes daily more marked. It has become necessary to look to Madras for our Sepoys instead of to the fighting races of the Punjab and Upper India, and a bounty of 50r., or nearly £5, has been sanctioned for all recruits. For a native soldier to receive this

(a) "The Surgeons' Pocket Book." By Surgeon-Major J. H. Porter, late 97th Regiment; late Assistant Professor of Military Surgery, &c., &c. Charles Griffin & Company. 1880.

amount on enlistment is equivalent to a bounty of £50 being offered to a recruit in England.

"British" Cholera in Simla.—The *Times of India* of June 26 says that "At Simla everybody, including Lord Lytton and his family and the Viceroy, and most of the members of his staff, are suffering from an epidemic which is said to somewhat resemble British cholera." What is the cause of this outbreak? Is it the water again?

The Medical Institutions of Calcutta.—The report for the year 1879 on the Medical Institutions of Calcutta has been published, and contains many facts of general interest. The general health condition of Calcutta during the year in question was better than in 1878, the municipal returns showing the death-rate to be in 1879 30 per 1,000, and 38 per 1,000 in the previous year. Except during the first quarter of 1879 there was no exceptional prevalence of small-pox as there had been the year before, and the great fever mortality of 1878, which was evidently connected with dear food, was not repeated. This improvement in the general condition of the city naturally led to a falling off in the numbers requiring hospital treatment, the total number of patients treated being 265,018, that is some 21,500 less than in 1878, and 34,500 less than in 1877. Mahomedans and Hindoos are, of course, the classes of the community from whom the great bulk of the patients are drawn, but the Surgeon-General remarks that the table showing races is not of much value as a test of the prevalence of disease among the different classes of the community, owing partly to the indefinite way in which Eurasians and native Christians are returned both in the hospital books and the census papers, but chiefly because hospital admissions, being regulated by the available accommodation, cannot be a safe guide to the health conditions of the classes represented by the patients received. Malarious fevers proved less fatal than in 1878, as well as less prevalent. Diseases of low condition and debility were of equal prevalence, but much less fatal in 1879. Cases of dropsy presented themselves in unusual numbers, but were very fatal. Respiratory affections, though equally prevalent, were less fatal than in 1878. Cases of dysentery and diarrhœa were less numerous than in the former year, but showed a very high death-rate. On the whole, it appears that although there has been a slight relative improvement in 1879, Calcutta has, since 1874, become more unhealthy, as regards serious fevers, than it was in 1871-73. With reference to the above, we can only add that the circumstance of the capital city of India having increased in unhealthiness furnishes a very remarkable commentary upon the *sanitary* improvements which at great cost have lately taken place in connection with it.

Fever at Mhow.—Malarious fever is said to have broken out among the British troops at Mhow, a large military station in Central India. We can understand that this designation really represents the actual nature of the fever which, in reports from India, has for some years back been described as *typhoid*, leaving the conclusion uncertain whether by that term be indicated a low adynamic form or stage of endemic fever, or a specific form due to pythogenic causes. The past history of Mhow teaches us that outbreaks of "malarial" fever occur at intervals there, and that on some occasions they are of great severity.

Indian Medical Officers.—Surg.-Major Hunter Adam, of the 10th M.N.I., proceeds on two years' sick leave to Europe. Surg.-Major Bilderbeck is to succeed him as senior medical officer in charge of the Rumpa Base Hospital, and Surg. D. S. E. Bain has been directed to proceed to Rajahmundry and take charge of the 10th M.N.I.

Designation of Surgeons-General.—At the suggestion of the Surgeon-General with the Government of India, the following designations have been assigned to the officers concerned:—Surgeon-General with the Government of India; Surgeon-General with the Government of Madras; Surgeon-General with the Government of Bombay; Surgeon-General, Bengal; Surgeon-General, North-West Provinces and Oude; Surgeon-General, Punjab; Deputy Surgeon-General, Central Provinces.

Two cases of sunstroke have occurred at Simla—Dr. Hannan, Officiating Deputy Surgeon-General, Umballa Division, and Dr. Young, of Meerut. We regret to learn that Dr. Hannan died at Simla on 14th of June.

Deputy Surgeon-General Van Someran and Deputy Surgeon-General Theobalds, both of the Madras Army, were recently promoted to Surgeon-General by brevet, on retirement. Surgeon-Major Frances Day, F.L.S., of the Madras Army, and formerly Inspector-General of Fisheries in India, who retired from the service in 1876, has, after an interval of four years, been granted a step of honorary rank, and gazetted Deputy Surgeon-General in recognition of his services to science.

Manufacture of Quinine.—According to a Darjeeling paper the Government will soon be in a position to manufacture all the quinine required for the public service in India on its own plantations, as Mr. Gammie has succeeded in manufacturing quinine at Rungbi fully equal in colour and general appearance to any produced by European manufacturers, and what really is of as much importance to the country, at an almost nominal cost. The present retail price in England of Howard's quinine is from 13s. to 14s. per ounce, and the price has been as high as 16s. to 18s. The cost of the Rungbi is estimated at 2 rs. per ounce.

Movements of Medical Officers in India.—Surgeon-Major W. H. Colvill, Bombay Medical Service, in medical charge 21st N.I., is allowed furlough to Europe for 2 years, on medical certificate.—Surgeon-Major W. H. Harris, Madras Medical Service, is granted extension of leave for six months, on medical certificate.—Surgeon-Major D. V. Smith, Indian Medical Service, Bengal, to Hills in India, from June 8 to Dec. 8, on medical certificate.—Surgeon-Major J. J. Durant, principal assistant to opium agent, Benares, is allowed leave for forty-four days, from July 17.—Dr. P. J. Freyer is appointed to act as principal assistant to opium agent, Benares, during absence of Dr. J. J. Durant.—Surgeon J. S. Gunn, M.B., medical officer, 4th Bengal Cavalry, is appointed medical officer, Lawrence Military Asylum, Sanawar.

Correspondence.

ENTERIC FEVER AT NATAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your journal of 28th July, 1880, a paragraph informs your readers that "enteric fever is very prevalent at Natal, several officers and privates having succumbed to this *zymotic* during the last few days." With reference to the discussion now taking place on the subject of enteric or typhoid fever, will you kindly give me space in your columns to suggest that it may be clearly stated what is the precise sense in which the term *enteric* is made use of in that paragraph? What are the grounds upon which the prevailing fever is looked upon as *zymotic* in origin or nature?

According to Surgeon-Major A. Clark, many of the cases of "typhoid" fever which prevailed in Natal and Zululand in 1879 "occurred in healthy camps on ground previously unoccupied (virgin soil), and in bodies of picked men." He further states that several medical officers "maintained that it was *not* typhoid as commonly understood in England, but bilious remittent with *typhoid symptoms*, as seen in India. Others nailed their colours to the mast that it was genuine *enteric*." Surgeon-General Wolfreys, C.B., describes this fever as typho-malarial, and expresses the opinion "that it is climatic, the true autumnal fever." Also that "in fatal cases the lesions of Peyer's patches are well-marked." Sir Joseph Fayrer, K.C.S.I., commenting upon the above remarks, observes: "These facts seem to show that enteric fever cannot be always ascribed to a 'filth' cause, but that *climatic*, or what is embraced in that unknown word malaria, may give rise to it, as it undoubtedly does to intermittents, remittents, and possibly cholera." According to Surgeon-Major Down, "in the late Zulu war cases of enteric fever occurred in detachments of our young soldiers, which no theory of specific contagion could explain, and which were usually vaguely accounted for on the pythogenic theory of foul drinking water. In short, I think there can be no doubt that enteric fever cases constantly crop up in hot climates, the causation of which is inexplicable, either by the theory of propagation or of pure pythogenesis."

Thus the pertinence of the two questions submitted in the opening paragraph of this communication is, I trust, made apparent.

I am, sir, yours, &c.,

C. A. Gordon, Surgeon-General.

70 Cambridge Gardens, W.

THE NEW OPHTHALMOLOGICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I feel that it would not be just to Mr. Vose Solomon that those ophthalmic surgeons who are of his opinion respecting the metropolitan exclusiveness of the new London Ophthalmological Society should remain silent; and I therefore beg to say that I entirely concur in the view expressed by him that it is greatly to be regretted that an attempt at scientific fraternisation amongst British ophthalmologists should be marred by the deliberate exclusion of the profession outside London. Without venturing upon an assertion which the exclusive majority of the Society would consider audacious, that the ophthalmic specialists of the large towns throughout the kingdom are as well worthy of confidence and consideration as their London *confrères*, I think that at least they hold generally a scientific position which should entitle them to toleration; and I am sorry that the majority of those present at its inaugural meeting have thought it desirable or necessary to record a contrary opinion.

I am, sir, yours, &c.,

ARCHIBALD HAMILON JACOB, M.D. Dub., F.R.C.S.I.,
Oculist in Ordinary to His Excellency the Lord Lieutenant.

Dublin, July, 1880.

Novelties.

BENHAM'S STEAM ANTISEPTIC SPRAY PRODUCER.

THE hitherto invented apparatuses for the production of antiseptic spray during surgical operations have been in one way or other defective; but we can confidently recommend the instrument introduced by Messrs. C. Wright and Co., of 108 New Bond Street, who are the sole manufacturers. The engine is wholly of metal, and provided with a gauge for ascertaining the water level in the boiler. It is fitted with an improved handle to facilitate easy holding, and will produce an uninterrupted spray for above an hour continuously. It is, moreover, exceedingly cheap, being supplied for 15s. 6d. in a box, and is in every respect eminently fitted for the purpose it is intended to serve.

CHRISMA.

UNDER the name "Chrisma," Messrs. Allen & Hanburys, manufacturing chemists, of Lombard Street, have introduced a substance for use in the preparation of unguenta, &c. It is a pure hydro-carbon, the product of petroleum, and is admirably adapted to replace the old-fashioned and less dependable bases of the Pharmacopœia, answering as it does the requirements of consistency and cheapness, and especially because it possesses neither taste nor smell. Kept for a long time it retains its bland characters, does not become rancid, and even in warm weather can be used without many of the disagreeable experiences to which the employment of lard introduces the dispenser. Chrisma is undoubtedly one of the most perfect substances of its kind with which we are familiar.

THE KEPLER COMBINATIONS.

THE Kepler brand of Malt Extract is now so well known that little need be said in recommendation. The manufacturers have, however, introduced recently some combinations, in the shape of cod-liver oil, citrate of quinine, beef and iron, the hypophosphites, and pepsine, the efficacy of which some of our readers will doubtless be glad to test. We have lately tried the kepler and pepsin combination in a case of almost chronic dyspepsia, with emaciation from mal-assimilation of food, with excellent results.

SYMINGTON'S COFFEE PREPARATION.¶

OF the many preparations of coffee before the public, those prepared by Mr. T. Symington, chemist, Edinburgh, rank foremost. Especially the essence of coffee and the combination of coffee and milk are deserving of praise; with the former a cup of most delicious coffee can be immediately prepared by the addition of boiling water; and the latter though a little more troublesome to make ready, forms an excellent and refreshing breakfast beverage. These articles are pure, palatable, and cleanly, and will be of great service in all cases where coffee is desirable for patients' use. For travellers, also, these concentrated essences will be found very handy. There is also made by the same firm a compound of dandelion and coffee. In the treatment of dyspeptic and bilious cases it is an admirable preparation.

AN EPILATORY FOR USE IN FAVUS.

IN an article on the treatment of the different forms of tinea, Dr. Claudat in his thesis proposes the following epilatory application in favus:—Prepared lard, 25 grammes; glycerine, 5 grammes; carbonate of soda, 4 grammes; powdered quick-lime, 2 grammes; powdered charcoal, ½-gramme. After a variable time, but rarely more than ten or twelve days, the skin assumes a rosy tint, sufficiently intense to assure us that we may commence the process of epilation. We may now seize with the fingers the hair which we have previously had cut short (about two centimetres long) and draw them out without the least pain. A lotion of corrosive sublimate may now be applied for eighteen days, and then an ointment of araroba.

Royal College of Physicians of London.—The following member was admitted Fellow of the College on July 29:—

Fox, Cornelius Benjamin, M.D. Edin., Ilfracombe.

The following candidates were admitted Members on July 29:—

Biss, Cecil Yates, M.B., Cantab.
Colquhoun, Daniel, M.B., Lond.
Gabbett, Henry Singer, M.B., Dub.
Horrocks, Peter, M.D., Lond.
Ludwig, G. H. W. R., M.D. Leipsic
Maclean, L. H. J. M.D. Heidelberg

The following were admitted Licentiates on July 29:—

Acland, Theodore Dyke
Adam, Caleb Denovan
Atkin, Charles
Capon, Herbert J., M.D. Brussels
Cree, William Edward
Davies, Morgan, M.B., Aberdeen
Dingley, Allen
English, Thomas Johnston
Faithfull, R. L., M.D., New York
Falla, Walter
Hamerton, George Albert
Hanson, John Edward
Hudson, Theodore Joseph
Lawford, J. Bowring, M.D.
Perkins, George C. Steele
Pilkington, Francis Sergent
Porritt, Norman
Richardson, Charles Boards
Ross, J. F. W., M.B., Toronto
Routh, Amand Jules McConnel
Sanders, J. W., M.D., Brussels
Stansby, Charles John
Sutcliffe, John
Ware, John William Langston
Warren, Henry Guy Seymour
Wigg, Alfred E., M.D., Brussels
Wilson, John

Royal College of Surgeons of England.—The following candidates for the Diploma of M.R.C.S. having passed the required examinations, were admitted Members of the College at a meeting of the Court of Examiners on July 22:—

Briscoe, J. Frederick
Clark, William
Corbould, H. Francis
Elliot, E. A. Savage
Ford, L. Frederick
Hendley, John Lupton
Hockin, George Treverno
Hoets, Alton Kingsley
Hills, A. Phillips
James, Charles Alfred
Jones, A. C. Brett
Morris, E. F. Griffith
Newnham, W. H. Christopher
Lloyd, Rickard William
Stansby, Charles John
Steeves, George Walter
Taylor, Henry Herbert
Wakefield, Horace

The following were admitted Members on July 23:—

Acland, T. D., L.R.C.P. Lond.
Batterham, John Williams
Coronado, D. E., M.D. Paris
Lane, Alexander
Milnes, George Hutchinson
Phipps, E. V. Ayre
Pizey, G. F. Price
Risk, E. J. Erskine
Street, A. F., M.B. Cantab.
Tucker, Joseph
Westcott, Sinclair
Wilson, George John

The following were admitted Members on July 26th:—

Barnes, George Frederick
Chitty, Alfred Goldney
Duncan, Duncan
Fenton, H. A. Hill
Grayling, Arthur
Lerew, Frederick William
Quicke, William Henry
Richardson, Richard Tippetts
Silk, J. F. William
Terry, Henry George
Weston, George Edward
Wood, Edward Archer

The following were admitted Members on July 27th :—

Clarke, Ernest
Clarke, William Jenner
Doyne, Robert Walter
Dobrsahian, Gabriel Sukias
Field, James William
Howard, Eaton Clark
Jackson, Mark
Jay, M. H. Hindmarsh
Jessop, W. H. H.
Nichols, F. P.
Taylor, Thomas Percy
Volckman, Ronald
Woodhouse, Tom Percy

The following were admitted Members on July 28th :—

Battiss, William Sullivan
Bradshaw, O. G Dix
Burton, F. H. Merceron
Carpenter, Arthur Bristowe
Carr, Alfred Alexander
Collins, William Job
Hayward, John Davey
Macnamara, Hugh Winckworth
Neumann, J.
Shepard, Ernest William
State, Alfred
Thompson, Charles Emilius
Welch, George

King and Queen's College of Physicians.—At the July examinations the following candidates obtained the licences in Medicine and Midwifery of the College :—

MEDICINE.

Beattie, James Henry
Beattie, Robert Ettingsall
Broadbent, George Harry
Butler, Fanny Jane
Cosgrave, Alexander
Dennehy, Patrick Richard
Dickenson, Augustus Newton
Elliott, Geo. Philip
Fitzmaurice, William Henry
Flanaghan, Hubert
Gibbon, William
Gilbert, William Frederic
Hall, Henry Wilson Stocker
Harricks, John Hugh
Kernan, James
M'Cullagh, John
Magee, William Joseph
Morgan, Anthony H.
O'Donaghue, Patrick
O'Dwyer, James Joseph
Renner, William
Sharp, Samuel
Tate, John Whittake
Wilson Henry Clark

MIDWIFERY.

Beattie, James H.
Beattie, Robt. E.
Broadbent, Geo. H.
Butler, Fanny Jane
Cosgrave, Alexander
Flanaghan, Hubert
Gilbert, William Fredk.
Hall, Henry Wilson Stocker
Harricks, John Hugh
Kerman, James
M'Cullagh, John
Manning, George Henry
O'Dwyer, James Joseph
Renner, William
Sharpe, Samuel

The following were admitted Members of the College on July 9th :—

Bridgford, Charles Trussell
Croly, Henry Gray
Elmes, Robt. R. King
Pendleton, Richard Warren
Robinson, Charles H.

NOTICES TO CORRESPONDENTS.

MR. WILSON.—See reply to another correspondent under the head of "Obscene Advertisements."

SWEATING OF HANDS AND FEET.—A correspondent sends us some leaves of the common plantain (*Plantago Media*), which he says are effectively used in his neighbourhood for the cure of sweating of the feet. They are placed inside the shoes and are said to harden the skin, and cure the excessive perspiration in a few days.

MR. J. F. P.—Our "Student's Number" will be issued on Sept. 22.

SURGEON-MAJOR CURRAN.—With pleasure.

DR. PILCHER, Brooklyn.—We cannot add further to our Exchange List.

DUBLIN SANITATION THREE-QUARTERS OF A CENTURY AGO.

A CORRESPONDENT sends us the following extract from a paper called "Ireland's Mirror," published in 1805. Knowing that Dublin scavenging cannot be much worse than it is, we offer to the Dublin corporation the entreaty of our common enemy. It may be assumed that the writer of the letter is about the same as he was in 1805, and experience of Dublin streets makes it obvious that the scavenging authority are also still unchanged, so that the letter would seem quite appropriate to Dublin as it is, and therefore not unsuitable for publication at the present time :—

"TO THE RIGHT HON. THE L—D M—Y—R.

"MY L——D,

"I understand your L——ds—p intends cleansing and purifying the streets of this city; although this has for some time occupied your L——ds—p's mind, I have not seen it put into practice, at which I rejoice exceedingly, and ask it as a favor that your L——ds—p will be so obliging to me as not to carry it into effect; and the result of your gracious compliance in this shall be, a most glorious plague will break out thro' the whole city next summer; hundreds, nay thousands of the inhabitants will then be swept home to my nefarious kingdom; and should you cleanse the streets my dominions must remain unpeopled a considerable time longer.

"Do, my dear L——d M—y—r, suffer the dunghills to increase and enlarge, and the filth to abound. When summer arrives then the baleful pestilence shall surely go forth. I shall have the diabolical pleasure of seeing all the streets darkened with the solemn processions of the dead; every house shall resound with the sweet harmonious notes of dying groans; my kingdom shall be greatly enlarged, and Dublin depopulated. "I am, my L——d,

"your L——ds—p's sincere Friend, &c.

"March 9th, 1805. "OLD NICK,"

DR. SHOEMAKER, Philadelphia.—See reply to Dr. Pilcher.

A MEMBER.—We shall be duly represented at the meeting.

OBSCENE ADVERTISEMENTS.—A correspondent draws our attention to the persistence of some of the leading Dublin papers, notably the *Irish Times*, in inserting advertisements of the filthy literature of the quacks. Our opinion has been oft expressed on this distasteful subject, and we can but reiterate our protest against the encouragement given to vice by the acceptance by journals which ought to be above it, of the ill-gotten gains of quacks of the type of the notorious Dr. (!) Henry Smith, of 8 Burton Crescent, or the nameless "Vital Regenerator" of Berners Street, London. On one occasion we made the discovery that, under the cover of an innocent-looking advertisement which was current in the Dublin papers, a book of a most obscene and immoral character was being circulated amongst the youth of both sexes in Ireland. We thereupon wrote to the editors of the Dublin papers stating the facts, giving proof, and suggesting the withdrawal of the advertisement. The *Daily Express* alone complied, and for months afterwards, and we believe to this day, the *Irish Times* continued to print the advertisement in question. So much for newspaper morality in Dublin!

RAISING THE WIND IN A NEW WAY.—The subjoined advertisement, taken from the *Bazaar*, has been forwarded to us from more than one source :—"W. Alfred Johnson, M.D., L.R.C.P. (Edin.), L.S.A. (Lond.), Member of the General Council of St. Andrews, Author of 'Practical Economy,' now running every Wednesday in the *Bazaar, Exchange and Mart*, will be pleased to answer any questions, medical or surgical, or on natural history, 1s. each letter.—Hereford Road, London, W."—"The clerks of Dr. Johnson, Author of 'Practical Economy,' now running through the *Bazaar, Exchange and Mart*, every Wednesday, will be pleased to answer any questions referring to housekeeping, furniture, decorating, repairing, &c., all kindred subjects, also photography, painting, and electro-plating at home, &c. Price 1s. each letter.—Hereford Road, London, W."

VACANCIES.

Chipping Sodbury Union.—Medical Officer. Salary, £35, with the usual extra fees. Applications to the Clerk of the Union before August 11.

St. George's Hospital, London.—Surgeon and Assistant Surgeon. Honorary. Candidates, who must hold the F.R.C.S. of England, to send in their applications to the Secretary before August 12.

Warneford Hospital.—House Surgeon. Salary, £100, with board. Applications to the Secretary at Leamington before August 9.

APPOINTMENTS.

BEATTY, W., M.B., Resident Surgeon to St. Mark's Ophthalmic Hospital.

GRIMWOOD., H. C., M.R.C.S.E., Medical Officer for the First District and the Workhouse of the Pontefract Union.

HININGS, J. W., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer of the Knightwick District of the Martley Union.

HORNE, A. J., L.R.C.S.I., L.K.Q.C.P.I., Assistant Physician to the Rotunda Lying-in Hospital.

HUGHES, T. J., M.D., M.R.C.S.E., Medical Officer for the West Woolwich District of the Woolwich Union.

JACKSON, G., F.R.C.S., Hon. Surgeon to the Plymouth Public Dispensary.

JONES, T., M.B., F.R.C.S., Hon. Surgeon to the Royal Manchester Infirmary.

MACAULAY, R., M.D , Medical Officer to the Ballina Union Workhouse.

MCCLURE, H., M D., M.Ch., Medical Officer for the First District of the Romford Union.

MOORE, H. C., M.B., House Surgeon to the Lancaster Infirmary.

O'SULLIVAN, S., M.D., M.Ch., L.R.C.S.Ed., Visiting Surgeon to the North Infirmary, Cork.

O'SULLIVAN, M. U., L.R.C.S.Ed., Medical Officer to the Mohaliff Dispensary, Killarney Union.

PHILLIPS, J. W., M.R.C.S.E., Medical Officer for the Cowbridge District of the Bridgend and Cowbridge Union.

SLOMAN, S. G., M.R.C.S.E., Medical Officer for the South District of the Farnham Union.

SOUTHAM, F. A., M.A., M.B., F.R.C.S.E., Hon. Assistant Surgeon at the Manchester Infirmary.

WARE, J. W., M.R.C.S.E., L.R.C.P.L., House Surgeon to the North Devon Infirmary.

WATSON, G. S., M.B., C.M., Medical Officer for the Thaxted District of the Dunmow Union.

Births.

ARMSTRONG.—July 26, at Hazlehatch, co. Kildare, the wife of Deputy Surgeon-General W. Armstrong, of a son.

ARNOTT.—July 29, at Walworth, the wife of Sandford Arnott, M.R.C.S., of a son.

MACDONNELL.—July 24, at The Glen, co. Sligo, the wife of Hercules MacDonnell, M.D., Dundalk, of a son.

ROCHE.—July 26, at Mount Clarence, Kingstown, the wife of Surgeon J. Roche, M.D. (retired Bombay Army), of a son.

STACK.—At 10 Westland Row, Dublin, the wife of R. Theodore Stack, M.D., of a son.

Deaths.

DODD.—July 23, at Kenmare, co. Kerry, Henry F. Dodd, L.R.C.S.I., aged 27.

PHELAN.—July 23, at his residence, Rock Ferry, Cheshire, Wm. Bernard Phelan, L.R.C.P.E., L.R.C.S.E., &c.

SAUNDERSON.—July 22, at Union Lodge, Scarva, co. Down, William Saunderson, M.A., M.B., T.C.D.

TREVAN.—July 18, at Padstow, Henry Trevan, F.R.C.S.E., Fleet-Surgeon, R.N. (retired).

WALSH.—July 24, at Whitechurch, near Dublin, Albert J. Walsh, F.R.C.S.I.

Abstract of Two Lectures

ON THE

ETIOLOGY OF TRUE LEPROSY.

Delivered at the Royal College of Surgeons, June 25th.

By Professor JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital.

LECTURE II.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I passed in review the principal facts connected with leprosy, and these facts seemed to lead to the conclusion that the disease must be due to some article of food; at all events I endeavoured to exclude other causes, and I hope succeeded in proving that we could not otherwise account for its former wide distribution, gradual disappearance, and present continuance in certain districts. We found that it occurred in very different climates and in persons of very different habits and positions in life, so that it could not be accounted for merely by hard living or bad food. The disease is said to be hereditary, but it is not simply hereditary, it can be induced in persons born and bred in England, but who have gone to reside for a comparatively short period in an infected district. Yet it does not affect all who are thus exposed—it picks out one here and another there—it may be only one in a family. We must now ascertain, if possible, what special kind of food it is which induces the disease.

Very various articles have been thought to have a share in the production of the disease. The use of milk in a state of decomposition has been suggested as a cause. Milk is used in excess in some districts where leprosy prevails, but not in all; and then one would expect to find the disease at least as common inland as on the coast; but, with some apparent exceptions, to which I shall refer presently, the disease is most common on the coast. The Norwegians are certainly fond of decomposed cheese, but so are the inhabitants of some parts of Germany where no leprosy exists.

Pork is another article of diet which has been thought to be a cause. But the Jews who eat no pork, are not exempt from leprosy, nor are Mohamedans who also abstain from this meat. It has been said that my theory—that fish is the cause—cannot be true because Jews and Mohamedans do not eat fish; but this is a mistake, they do eat fish—that is, certain kinds of fish.

The excessive use of *maize* has been thought to account for the prevalence of the disease; but leprosy prevails where maize does not grow. The same has been said of rice, but there is the same objection: a person writing about the disease in India may be pardoned for coming to this conclusion, but anyone reviewing the whole subject here in London can see at once that these views are untenable.

The use of *bad corn* has been suggested as a cause, but bad corn is eaten in places where leprosy does not prevail. Pellagra is certainly due to the use of diseased maize, but this is not leprosy.

I need, however, scarcely mention all the articles of diet upon which suspicion has fallen, but will at once proceed to state the conclusion at which I have myself arrived and that is, that fish is the one sole cause of leprosy. I do not mean to assert that the use of fish always causes leprosy, but that some poison generated in connection with fish causes the disease. How does this hypothesis agree with the chief facts relating to the natural history of leprosy We find that nearly everywhere the disease is most common on the seashore, and that when it spreads inland it generally occurs on the shores of lakes, or along the course of large rivers; we find also that fish is largely eaten wherever leprosy prevails. I don't believe that any other article of diet has any influence whatever on the causation of the disease; this is so special in its character that it seems evident that it must have one special cause. I believe, however, that certain conditions greatly modify the action of this cause. We see that draymen drink an enormous quantity of wholesome beer before they suffer from gout, but others who obtain their beer under less favourable conditions get gout though they drink but little. And so with the fish: in some places we find that a large quantity is required to produce leprosy, in others a small

quantity will suffice. Fish bred in warm waters seems to be more dangerous than that found in cold; fish in a state of decomposition is more dangerous than fresh fish, and fish in a special state of decomposition is very dangerous; the crustacea, although strictly speaking not fish, are also very dangerous. As regards the history of the disease we know that the Egyptians, amongst whom leprosy prevailed at a very early date, were large eaters of fish. The Hebrews, we are told, wept over the memory of the fish they had eaten in Egypt: they acquired the habits of the Egyptians, and they acquired leprosy. The same cause probably prevailed among other old races.

But we find that leprosy faded away before the advance of agriculture, and that now it is only met with in certain districts; that it prevails amongst the well-clothed and the ill-clothed, in cold countries and in hot, and that the only constant factor is the diet. I may remark that amongst a rude people the first food available in any large quantity is fish; it is easier to catch fish than to kill wild animals, and besides a supply of fish is accessible at times of year when nothing else can be obtained. Then we find that savage people like decomposed food: the only article of diet which we now eat in a decomposed state is game, but our forefathers liked many other things "high" which we should now consider unfit to eat; decomposed fish used to be considered a delicacy.

As the population increases fish becomes scarce: the seaboard remains the same, and the available supply has to be divided amongst a greater number. At the time of the Reformation, when the eating of fish on certain days ceased to be obligatory, the fishermen were afraid that their living would be gone, and laws were passed for their protection. Who would think of such a thing now? The constant cry is that fish is so dear, in spite of increased enterprise and improved transport the supply cannot equal the demand. Then, as might be expected, the consumption of the coarser kinds of fish diminishes as other kinds of food become accessible: this especially applies to inland districts—as the population increases fish becomes a luxury inland, and so we find that, as a rule, leprosy disappears earliest in inland districts, and lingers longest on the coast.

As civilisation advances roads are improved, and there are increased facilities for transit. This acts in two ways in checking the prevalence of leprosy—first, it increases the area over which the supply of fish is spread, and increases the demand, and secondly, the fish is delivered in better condition, and is less likely to become decomposed before it reaches its destination.

Next, how does the fish theory accord with what is known about the present distribution of leprosy?

First, in Europe: in Norway leprosy is most common at Bergen, a town which boasts of the largest fish market and the largest leper house in the kingdom. At Christiania the disease is unknown, except from imported cases. Leprosy begins to be endemic at the point where the Gulf Stream strikes the coast; here the fiords do not freeze in winter, though further south they do. As we go north the disease gradually becomes less common. The land in this part of the country is poor and rocky, and the inhabitants live almost wholly on fish. Dr. Danielssen, a Norwegian physician, gives the following account of their diet, I quote from Dr. Liveing's book:—

"Herrings are generally used in a salted state, rarely, if ever, are they eaten fresh. The peasant of the western coast is so little delicate about this article of food, which forms so large a proportion of his daily sustenance, that he often devours it in a putrid state. When the herring fishery happens to be in places where assistance is not at hand, as is often the case in North Bergen, a large number of herrings are thrown on shore and left for many days waiting for purchasers. Should these not appear, the peasant appropriates the fish to his own use, and adding a small quantity of salt to the half-rotten herrings, conveys them home. After the lapse of some weeks these herrings are in a manner pickled, that is to say, they are in a state of decomposition, and then they become the daily food of the whole family. Each week, until they are consumed, they become more and more decayed, but nevertheless the nauseous food is eaten till not a herring is left. Nay, so constant is this hateful custom among the peasantry that they will not touch fresh fish, but prefer to leave it for some days till incipient decay gives a zest to their coarse palates."

"The truth of the latter part of this statement," adds Dr. Liveing, "I can fully bear out from my own observations." If disgusting and half-rotten animal food has any influence whatever on the development of leprosy, the west coast of Norway is, of all countries, the most favourably circumstanced for its production."

In the Faroe Islands leprosy has been rapidly disappearing since the inhabitants gave up the herring fishery and took to agriculture, and in Sweden, where it once prevailed extensively, it also died out after the cessation of the herring fishery at the beginning of this century, and now only lingers in one fishing village.

In Russia leprosy is met with only in two districts, one in the north and the other at the extreme south, both on the seaboard. In the rest of Europe it exists only in the part of Norway to which I have referred, in Iceland on the side which is washed by the Gulf Stream, but not in the north and east, and the headquarters of the disease is a fishing town. It is met with also in a few places on the Mediterranean: when I was at Bergen I saw a vessel in the harbour, which had brought a cargo of copper ore from one of the Spanish seaport towns where leprosy is still seen, and it was being loaded with a return cargo of fish.

In Madeira the disease is thought to be due to poverty with uncleanliness and unwholesome food. Yet, though four-fifths of the inhabitants are very poor and live badly there are only eighteen lepers on the island, and of these one is a clerk in a wine store who has not been subjected to any privations. But if you should visit the island residents will warn you if you meet a peasant carrying a basket up from the shore to keep to windward of him, as it may probably contain stinking fish which is a recognised, and with some a favourite, article of diet.

In India leprosy is very prevalent, and it is here that the apparent exceptions to the fish theory are most numerous. The disease prevails to some extent everywhere: it is most common in the neighbourhood of Calcutta, next on the banks of the Ganges, and next in order comes Nepaul. The facts collected in the Report on Leprosy of the Royal College of Physicians respecting the conditions under which the disease prevails in India are very valuable. With some exceptions it is found that leprosy prevails most in districts where the population is poor and fish diet is common, as along the course of the larger rivers, and in places where much preserved fish is consumed. In opposition to the fish theory mention is made of a Somali tribe who suspected that fish-eating caused leprosy, and accordingly have for a long time abstained from fish entirely; yet a few cases of leprosy still occur among them. But I don't think that this tells against my theory but rather in its favour; for it is evident that leprosy must have been formerly very prevalent amongst these people or they would not have thought of submitting themselves to such a restriction of diet: now the disease is slight. I may add that the same suspicion with regard to fish was current in Cornwall, and in other places where the disease occurs.

Then we have found that it is incurable where it originates, but is curable elsewhere. I have mentioned the case of the lady from Jamaica who had suffered severely from leprosy, but was cured after a residence of twenty years in England, and I mentioned also the case of the Norwegian immigrants in America. I suggested that this incurability must be due to a persistence of the cause. What is the diet in the leper houses? At Bergen I found that the patients had fish three days a week. In British Guiana we are told that they have fish every day, and in Barbadoes "salt fish daily!"

One of the principal objections which has been brought against this theory is, that leprosy prevails inland, in places where the consumption of fish would not be sup-

posed to be great. It is true that the disease does prevail in inland districts to a certain extent, but it is not so common as on the coast, and wherever it occurs fish, either fresh or preserved, is easily accessible. Some of the statements made in opposition to my explanation of the etiology of leprosy have certainly been very reckless. Thus Dr. Day, who holds high position as a naturalist in India, and is especially an authority on the subject of fish, tries to confute me by saying that, although the Burmese consume large quantities of nga'pee (preserved prawns), yet he had never seen a leper in Burmah, and that the disease is as common in the inland districts of India as it is on the coast. As to the latter statement I have already admitted that the distribution of leprosy in India does show some remarkable exceptions from the general rule that the disease is most prevalent on the coast, but as regards the first assertions that leprosy does not exist in Burmah, I find on turning to the Census return that the proportion of lepers to the rest of the population is larger in British Burmah than in India, and it is stated with reference to this prevalence of the disease that the inhabitants are neither dirty nor underfed, but that they are much given to the use of unwholesome fish. Colonel Yule, a high authority, says that 13,500 tons of nga'pee are consumed in Burmah every year. A patient of mine who had travelled in Burmah informed me that lepers swarmed all over the oountry, they were so numerous that the government did not know what to do with them. Dr. Day seems to have some peculiar ideas on the subject, for he speaks of "congenital leprosy"—there is no such thing as congenital leprosy—and says that he looked for the contraction of the fingers and toes which is seen in the children of lepers, a sign which has never been observed by me or, so far as I know, by any other observer.

This prevalence of leprosy in Burmah may I think throw some light on the cause of its prevalence in the interior of India. As we have seen elsewhere the danger from the consumption of fresh fish is comparatively slight, but from decomposed fish the danger is great. The prevalence of the disease inland is then probably due to the consumption of a small quantity of highly poisonous fish.

But I must pass on to say a few words about the disease in immigrants. One of my patients was a girl who had been born in the West Indies: her parents had been comfortably situated, and she had suffered no privations of any sort. Another was a boy who had lived some years in India in a comfortable home; I asked his mother if they had much fish at their table, and she answered that they constantly had it, for her husband was exceedingly fond of fish, and added of all the children this boy was the only one who resembled him in this respect. Another patient had been a common soldier: when I asked him if he had eaten much fish, he answered that he ate it whenever he could get it. Another was an officer who had held a command in the Straits Settlements. He said he did not care for fish, but was particularly fond of preserved prawns, and had had exceptional opportunities of indulging his taste. I might multiply these examples if I had time.

I know that leprosy has of late years invaded countries where it was not previously known, and that it has spread under conditions which at first sight do not appear favourable for it. Thus it appeared in the Sandwich Islands in 1848, and since then it has invaded California and Australia. It has followed the course of the Chinese: wherever they go the disease appears, and the explanation seems to be that wherever they go they carry their habits with them, and especially that they establish themselves everywhere as *cooks:* they are skilful cooks, and they can make use of many things which no one else would look at: decomposing fish and potted fish are amongst the delicacies in which they deal.

In conclusion, I can say truly that I shall be quite ready to hear any objections to this theory, and to discuss the subject fairly with anyone. At present I hold that all apparent exceptions can be accounted for, but if any one can bring stronger evidence against me than I can adduce in support of my argument I shall be quite ready to yield. But I must add that if this hypothesis can be disproved, I know of no other which can take its place.

ON FEVERS IN INDIA.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to Her Majesty the Queen.

With a view, if possible, to reconcile differences of opinion regarding the nature and etiology of what has of late years been termed synonymously *enteric* or *typhoid* fever as affecting British troops in India, I beg to submit the following remarks having reference to a paper on this subject that I had lately the honour to read before the Epidemiological Society, and to comments thereon in the *British Medical Journal*, of June 26th, 1880.

a. It has been said that in China "enteric fever was recognised as a distinct disease in 1859, but as no history of its incidence upon the natives prior to that date could be *ascertained*, it was *inferred* that it had been generated among the British forces who at that time were exposed to local conditions of excremental poisoning." I italicise the words *ascertained* and *inferred*, thus the better to indicate their relative force. The grounds are unstated on which the *inference* is based, but the following remark occurs at page 18 of my first special Report on Enteric Fever in relation to British troops in the Madras Command, namely: "Surgeon Mallachy, R.N., describing cases of enteric fever in the China station in 1874, alludes to the resemblance often seen between enteric and the low forms of malarial fevers on that coast, and is disposed to think that the distinction between these two diseases *is somewhat artificial.*"

b. It was stated that at Mediterranean stations "simple climatic causes did not lead to enteric fever unless indeed in special localities where fœcal influences also obtained." At page 18 of my first Report I quote from a paper which is given at length at page 205 of my second. According to that paper "in 1861 *epidemic* typhoid fever at Malta was considered due to bad sewage, overcrowding, defective sanitary arrangements *superadded* to miasmatic influences." Thus, in effect, the latter were the principal factors according to observers on the spot; but then, the disease so-called was epidemic, a special occurrence, while the conditions of sewage and general sanitation were constant. It is further added that "at Gibraltar, in 1868, remittent fever, common continued, and the enteric types were not always easy to distinguish." Here the exact sense in which the term enteric is used does not appear, yet from the context it seems to imply the fact of intestinal *complication* being present as opposed to the expressions "remittent" and "simple continued," in which that particular complication was not present. At page 82 of my second Report further details occur with regard to fever at Malta. Thus, "so far back as 1822, a fever to which the appellation *typhoid* was applied, was recorded as having prevailed among the troops on the island of Malta;" "previous to the rains the fever was of an ardent type," "after the rains the fever took in what was designated the *typhoid* type, and the cases then became less prevalent." On that occasion, Dr. Lightbody, of the 80th Regiment, thus indicated the exact sense in which he applied the term *typhoid:* "I apply it to cases of fever where there is no permanent symptom to guide the judgment of the practitioner, yet evidently great constitutional derangement, without perhaps any complaint save of lassitude and debility." In that sense the term was generally accepted until subsequently to 1859; since that date, as expressed at page 244 of my second Report, a *name* has been "applied in a specific sense in accordance with one particular complication out of many," namely, intestinal or enteric *complication.* But I must refer to page 82 of my Report, here quoted, for further details regarding fever at Malta.

c. It has been observed with regard to my paper "that attempts seemed to be made to identify a disease, now by means of some anatomical characters, now by means of clinical symptoms, or thirdly, by an appeal to considerations of cause;" also that the last means of identifying disease appear questionable. On these points, as more particularly detailed at page 236 of my second Report, I adopted the nosology officially laid down for my guidance, and in accordance with which the investigations undertaken by me were only a part.

As to considerations of cause, I observe that, as detailed at pages 3, 4, 6, 7, 240, and elsewhere in my second Report, the cause or causation of the form of fever I was called upon to investigate formed an important item of the definition laid down for my guidance. I observe, further, that although in civil practice, to quote from an authority named at page 15 of my first Report, that "the causation is so little understood that it gives us no help in the diagnosis of this disease," yet such investigations become a very important part of the duty of the army surgeon, involving as they do questions of general sanitation and of finance in connection therewith. In India the causation of diseases affecting British troops must ever be held as of the highest importance in relation more particularly to sanitary measures to be taken against their recurrence.

d. It has been said that in England, "Given, a continued fever with more or less diarrhœa and spleen enlargement, with special characters of temperature curves, with successive crops of rose-spots on the skin, and with certain anatomical characters in the fatal cases, we now know it as enteric fever." Granted, with regard to England, but with the remark that I beg reference to the long list of definitions of the disease so designated at pages 241 to 244 of my second Report, and to my remarks thereon in the latter, namely: "Here, then, I submit, in the enumeration given above, views are expressed with regard to causation and phenomena of so-called enteric or typhoid fever, absolutely differing among themselves." That the diagnostics thus enumerated do not apply to the cases recorded in my two Reports is stated in paragraph 10 of the paper read by me. Diarrhœa was neither constant in, nor characteristic in the cases recorded in my Reports; spleen enlargement in India is one of the most frequent results of malaria, and in the case of children is by no means seldom present without fever having manifested itself at all. As regards temperature curves, three different *standards* of these are given at pages 5 and 6 of my first Report; in my second Report a series of charts are given in connection with the cases recorded in that document, and from the whole I hold that the conclusion No. 14 of my paper on the subject is completely justified, namely, that "in three so-called typical charts severally extracted from the works of recognised authorities on enteric fever, the line markings differ from each other absolutely in their character; similar differences occur also in the temperature charts attached to reports of particular cases described as of that disease." As to rose-spots, I refer to the following extract from Deputy-Surgeon-General A. Smith, at page 104 of my second Report, namely, "as regards the information to be derived from the presence of eruptions on the bodies of men suffering from fever in a warm climate, it should be borne in mind that this form of evidence must be received with extreme caution, as it is well known to everyone who has had charge of European troops that it is the rule in India to find the body of every man suffering from any form of severe disease during the hot weather,—and it is in the summer and early autumn months that the majority of the more serious forms of fever occur,—covered with a heat eruption in one form or other, which might, perhaps, be mistaken for one of more serious import." Further remarks occur, not only in that paragraph, but at page 3 of my first Report, which seem to me to justify my conclusion 15 of my paper, namely, "that in the cases recorded of so-called enteric fever in Madras different kinds of eruption took place, but their relation to disease of Peyer's glands was not demonstrated by statistics; also that eruptions, precisely similar in nature, occurred in other forms of disease, and in the absence of any apparent disease whatever." On the subject of anatomical characters, I remark that this important point obtained very careful consideration in paragraphs 13, 16, and 39 of my first Report, and 27 of my second. As observed in the latter, pages 68 and 69, "the phenomena usually believed to be characteristic of enteric or typhoid fever are found during life and after death in various forms of intestinal inflammation, which result from non-specific causes;" also "Surgeon-Major Curran, A.M.D., adverting to Peshawur fever, says experience has taught him that morbid anatomy is not always to be trusted as a guide to the cause of death; very similar textural changes are produced by widely different systemic diseases." Further particulars to the same effect are given at the places quoted; they are too long to be here reproduced, but I consider that they justify my seventeenth conclusion in my paper alluded to, namely, that "specific pathological conditions of Peyer's glands, and of the mesenteric glands are (by some authors) described as constituting the distinctive character or *essence* of enteric fever; according to other authors, conditions undistinguishable from those found in the bodies of persons who have died by specific typhoid or enteric fever occur also in those who have died by other diseases and by certain poisons; further, that cases of *typhoid* fever are recorded as occurring in persons at an age beyond that in which Peyer's glands are present."

d. "It was perfectly permissible to regard much of the described fever of India as being identical with European 'enteric fever.' It was modified no doubt by circumstances of Indian life, yet did not appear to differ more from our own enteric fever than one outbreak might differ from another case, or from another outbreak of this multiform disease when it was witnessed in Europe." If the nomenclature of a disease be permitted to be so enlarged as to include *multiform* types, then in that case it is easy to comprehend how it is that the one hundred and four different *standards* of typhoid or enteric fever enumerated at pages 241 to 244 of my second Report have come to be adopted by different men. But, as already observed, the particular disease I was directed to investigate was "a specific form of fever due to the presence of filth in air, earth, or water" as distinguished from endemic climatorial fever attended by *enteric*, that is, *intestinal* complications. On this point, and as to the results of recent theories as compared to old, I give the following quotation from paragraph 19, page 244 of my second Report, premising that, as in other respects, so in respect to theories it is, I think, fair to judge of them by their results: "According to views expressed in the works of (the older) Indian medical officers, soldiers, and particularly those who were young and full-blooded, suffered from a fever, sthenic in its early stages, but in its later complicated with visceral derangement, intestinal, that is, enteric among others, accompanied by a low, typhoid, or adynamic state in those of weakly frame, asthenic from the first. That fever was formerly looked upon as the result of endemic and climatorial conditions acting upon individual constitutions and habits, and treatment was applied in accordance with those theories of its causation and nature. On the other hand, a *name* has been of late years applied in a specific sense in accordance with one particular complication out of many; that name, theoretically held to imply the presence of a particular type of disease, asthenic in nature, the result of a particular set of causes connected with filth, while in accordance with both theories remedial measures have been employed. According to the literature of this question, the present set of opinions with regard to India have been for some time back more and more discouraged, the latter more and more encouraged." And now for the result. It is thus officially expressed, namely: "It hence appears that of late years the proportionate *fever* mortality has increased nearly a fourth, and that the proportion of fatal

cases entered as enteric fever to all other fatal fevers has nearly quadrupled." Such being the case, I believe myself fully justified in writing as I do in continuation of the same paragraph—"Surely the circumstance thus stated is of itself sufficient to indicate the urgent necessity there is for a reconsideration of the whole question of pythogenic as against climatic and other endemic causation; that is, of the new *theory* as against the old *practice* regarding Indian fevers."

f. I am said to have stated that the continued fevers of India were but one single form of fever, whereas, at once I proceeded to divide them into as many as twelve groups. The divisions referred to occur at page 71 of my first Report; but surely the circumstance is plain enough that the distinctions there drawn are not with reference to *species* in the sense in which the terms *typhoid* or *enteric* are used; in fact, that they are so many expressions of *conditions*, not of species.

(To be continued.

Clinical Records.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.

Case of Popliteal Aneurism treated by Ligature of the Superficial Femoral Artery.

Under the care of Mr. P. J. HAYES, F.R.C.S. Ed.,
Surgeon to the Hospital, &c., &c.

THE following case is published as an addition to the numerous instances which prove the value of carbolised catgut for the purpose of ligaturing arteries affected by aneurismal dilatation.

A farmer, æt. 55, was admitted to hospital December 5th, 1879. He presented the appearance of a stout healthy man, but in reality his constitution had been impaired by rather intemperate habits. According to his own account he enjoyed good health until about fourteen months before his admission, when he observed a slight swelling in the left ham. This swelling appeared, or at least attracted his attention, some short time after his leg had been hurt by the kick of a young horse. He soon began to experience inconvenience whenever he walked for a length of time, as then the affected region became rather painful and the limb below increased in size. Six months after the appearance of the tumour the patient noticed pulsation in it, of course its enlargement was progressive, and distressing tension of the limb became notable after exercise. Early in the month of November, when walking through a field, he slipped or stumbled over a stone, immediately he was seized with a violent pain in the ham, which, however, gradually subsided, and disappeared within twenty-four hours. The man now consulted my friend and former pupil Dr. C. Segrave, who at once diagnosed the presence of popliteal aneurism, and asked me to see the case in consultation. At our meeting we agreed that as the patient could not submit to regular treatment for some days, the then enormously swollen leg should be bandaged with Dr. Martin's rubber rollers, and every attempt made to protect the weakened vessels from undue strain. It is not necessary to write any lengthened description of the aneurism. The tumour was about the size of a small orange situated in the upper or femoral portion of the popliteal space. Pulsation was strong, bruit distinct, and the sac was judged to be rather thin-walled. Martin's bandages were productive of good, inasmuch as venous congestion was very much reduced by the pressure, and when the patient presented himself for admission at Hospital, the volume of the left leg was but little in excess of the normal degree. Before being subjected to systematic treatment the patient was carefully examined, he seemed free from organic disease, but the heart's action was found to be both feeble and slow. The man was of a fidgety anxious disposition, very urgent in his demand to be treated by the most expeditious method possible, and soon it was discovered he did not bear the exhibition of opiates in a satisfactory manner. As regards treatment instrumental compression of the femoral artery was the first employed, then digital pressure, next flexion, and for a short time Esmarch's bandage was applied. I must say fair trial was not given to any one of the above measures. The man would not tolerate the use of such for a sufficient period. Twice he broke Cartes' compressor, he loosened the bandage, and, indeed, declared in very positive terms his desire that the artery should be tied.

On December 16th I proceeded to operate. The patient was brought under the influence of ether by my colleague, Mr. Kennedy, and I was assisted by Dr. Nixon and Mr. Coppinger. The artery was easily exposed near the inferior angle of Scarpa's space; then, having carefully opened the sheath, I grasped the outer edge of the small aperture between the blades of a forceps, and gently slipped the artery needle from without inwards behind the vessel. At my request, Mr. Coppinger, in like manner, drew inwards the inner edge of the sheath opening, and at once the point of the needle appeared. I then brought forward one end of the catgut ligature with which the instrument was armed, and before withdrawing the latter I compressed the vessel against it, whilst one of my colleagues ascertained that such pressure arrested all pulsation in the aneurismal sac. The ligature was tied securely, but without disturbing the connections between the vessel and its sheath. The wound was well washed with solution of carbolic acid (1 in 40). The edges were brought together by sutures of silver wire, and covered with lint squeezed out of carbolic oil. The limb was enclosed in suitable layers of cotton-wadding and flannel; position, heating, &c., were attended to, and the patient, who had not been removed from his bed, was allowed to recover gradually from the influence of the anæsthetic.

The only untoward consequences of the operation were, firstly, a slight blush of erysipelas, which appeared about the upper end of the wound, but which soon subsided without causing disturbance of the reparative process; and secondly, an attack of bronchitis which affected the patient during the second week after operation. Fortunately, he recovered so rapidly that he was able to return to the country Jan. 17th in the present year, one month after application of the ligature. Last April I heard from Dr. Segrave that the patient was quite well, but careless in his mode of living.

I have abstained from all needless description of operative details, but I wish to offer a suggestion or two, which may, perhaps, be of use to some of my junior *confrères*. In the first place, when it becomes necessary to raise the fibrous coverings of an artery, in order that they may be safely touched with a scalpel, I advise operators to seize the structures between the blades of a forceps at right angles to the course of the subjacent vessel, the raised tissue will then form a fold, transverse in direction to the axis of the artery, and all risk of including any texture other than the fibrous membrane will be avoided also. As the edge of the fold is the part to be incised, when the grasp of the forceps is relaxed, the length of the little wound will lie parallel to the vessel, and there can be no difficulty about the introduction of such an instrument as a director or an artery needle. I strongly recommend surgeons to employ Durham's retractors for holding aside the margins of the large wound. These retractors will be found far handier and more effective than are the old-fashioned bent spatulæ.

Translations.

DEAFNESS:

ITS DEGREES, CAUSES, AND THE VARIOUS MEANS RECENTLY DEVISED FOR DIMINISHING ITS INCONVENIENCES. (*a*)

By DR. LADREIT DE LACHARRIERE.

Translated by W. DOUGLAS HEMMING, F.R.C.S.ED.,
Bournemouth.

WE give the name deafness to a weakening or total loss of the faculty of perceiving sounds. Simple diminution of hearing has been called dysecia (δυς, difficult, and ακουειν, to hear), and complete abolition of the sense, cophosis (κωφος, deaf).

No infirmity brings with it more serious consequences. It not only deprives man of the delights of music and all the delicious sensations it provokes, but it condemns him to isolation. In the child it prevents the development of language or causes it to be forgotten. It arrests the pro-

(*a*) "Annales de Maladies de l'Oreille du Larynx," &c. 1880.

gress of the intelligence and places the child in a position of inferiority which he will feel ever after. If, in fact, sight enables us to appreciate and understand everything invested with form, all moral ideas and conceptions of the mind are transmitted by the sense of hearing.

Later on, when the child has conquered a language, which may be speech, mimicry, or writing, social life is in some measure brought within his reach; but what a time is necessary for the acquisition of the precious instrument! The child does not profit by the intellectual life which surrounds him. The man who has lost his hearing at a certain age does not resign himself to the isolation in which his infirmity places him, but the old man whose vision is enfeebled so that his powers permit only moderate exercise is buried in the silence which reigns around him. Life for him has no more charms. Man only appreciates the immense loss of hearing for which he will never be consoled when his misfortune is an accomplished fact. He does not trouble himself about a simple impairment of the organ, and generally only seeks for relief when the infirmity has become manifest. A wise hygiene would often have warded off an infirmity which science will frequently be powerless to remove.

Deafness may be congenital or acquired, the former always entailing deaf-mutism; with this important question we shall not now occupy ourselves. Deafness acquired during the first eight years of life places the child in similar conditions. Loss of speech is always the consequence unless the parents apply themselves with unceasing care to preserve the precious function of language to the child.

Sometimes deafness manifests itself suddenly and completely, but more often is slow and progressive in its march, which is in relation with the importance and degree of the lesion which causes it.

Patients usually appear little concerned at first, they do not attach much importance to impairment of the sense of hearing as long as there seems to be enough left; it is only when they are unable to follow a conversation, when they require things to be repeated, when in fact their infirmity becomes evident to all that they come under our care.

The disease sometimes attacks only one ear. While the affected ear is only impaired no great importance is attached to it, the sound ear sufficing to supply all needs; but when the loss of the sense is complete on one side whilst the other remains healthy, a phenomenon is produced which shows the importance of bi-aural hearing; persons so affected lose their notion of the direction of sounds. The double sense is absolutely necessary in man for the appreciation of direction. The auricle is not mobile as in most animals who turn it to receive all sounds, and who by this motion can recognise whether a sound comes from the right or from the left. The auricle of man has but very limited movement, and when one of the two ears is lost the whole head must be turned to recognise the direction exactly. This requires attention, and if the sound is momentary and is not repeated, it is impossible. I have proved the loss of this notion of the direction of sounds in many people. Hunting men are those who most often complain of it, as they are no longer able to recognise in a wood the direction of the chase or the sound of the passage of the game if they have not seen it.

The loss of an ear is not always a ground of exoneration before the courts of revision (for conscription). It should be always an obstacle to a military life, for the soldier will mistake in the night the direction of noises; what confidence, then, could be placed in his vigilance?

Diminution of the sense of hearing presents itself in very various degrees. *Apropos* of this I should mention the perversions of the auditory sense sometimes perceived. I have often found that some persons have lost the exact perception of certain sounds. I was consulted by a distinguished musician who heard the note "ut" a semi-tone too high, all the "uts" appearing sharp. I have also had under my care a lyric artist who, having had a transitory diminution of hearing power, had lost the idea of the correctness of sounds, and took all his notes too high or too low. I was happily able to cure him and enable him to pursue his career. These cases are exceptional, and most often the sense is simply enfeebled. Even in these conditions it should be remembered that some persons lose absolutely the appreciation of non-musical sounds, although they hear speech well, and can follow a conversation or a discourse. They are struck with the fact that they cannot hear their watch, for example, or any other equally slight sound whilst they continue to appreciate music as before. We must guard against this in measuring different degrees of deafness. It is indeed the watch which we first make them listen to, but it is the most insufficient instrument, if not the most faithless.

According to Von Tröltsch, in order to have an exact idea of the degree of hearing which a patient has preserved, we must take account of two things—viz., the distance at which the patient hears speech, and that at which he perceives the sounds of various instruments.

The human voice would certainly he the most natural means of appreciation if it were always alike. But are there two people in whom the tone, quality, intonation, rapidity or precision of speech are always the same? The human voice then can give us little help in the exact determination of the amount of deafness. Doubtless the physician might train himself to speak to his patients always in an almost uniform tone of voice, but how could he indicate the exact data which would make it useful to the many? How could he determine the extent to which low sounds or high sounds are perceived if there were some voids perceptible in the scale?

Not being able to utilise speech for determining with precision the amount of deafness, we have made use of the uniform sound of the watch and of certain instruments which have received the name of acoumeters.

The instrument most in use is the watch because it is always handy, and because it enables the patient himself to appreciate the progress of his infirmity. We ascertain whether it is heard only on contact with the ear, or at a certain distance. In order to appreciate with exactitude we must first determine the distance at which it is heard in the normal state, for there are no two watches whose sound is exactly similar in tone or intensity. There is another reason against the employment of a watch—viz., that there is no constant relation between the hearing of the tick and the hearing of speech. There are some people who hear speech well but who scarcely hear the sound of the watch at all. Von Tröltsch (*a*) thinks that, as a rule, those whose deafness dates from infancy hear the watch better than speech, whilst those in whom the lesion of the ear has only supervened at a more advanced age are more sensitive to speech. This rule, which is in the main true, nevertheless shows some exceptions.

A good acoumeter should fulfil the following very complex conditions according to Guerder. (*b*) It should be easily and quickly managed, should allow the appreciation not only of the intensity of sound, or the number of vibrations produced per second, but also the tone-quality and height, and the rapidity with which different sounds succeed each other.

Let us briefly notice the apparatus and methods which have been designed for this purpose.

Itard thought that his acoumeter would realise the conditions desired. It consisted of a metallic circle of uniform dimensions, which was struck by a ball of ivory fixed at the extremity of a metallic handle, the other extremity of which terminated in a needle traversing a graduated quadrant. This sonorous body being always the same it was possible by regulating the numbers traversed by the needle to produce a blow always of the same force, and consequently a uniform sound. The patient kept his eyes shut and raised his finger each time he heard the sound. It is needless to remark that this instrument, giving only one sound, it was impossible to appreciate with it all the modifications which the hearing might undergo. Von Ceuta (*c*) modified the conditions of the problem by seeking not at what distance a sound could be heard, but for how many seconds it was heard. He placed in the patient's ear an india-rubber tube, into the other extremity of which was inserted the stem of a vibrating tuning-fork. The tuning-fork being set in vibration by striking on the knee produced varying sounds; the instrument, therefore, was not always identical with itself.

Magnus (*d*) thought to avoid this inconvenience by fixing the tuning-fork and striking it with a small wooden rod. The sound-waves were collected by a sort of trumpet placed above,

(*a*) Von Tröltsch, *loc. cit.*, p. 255.

(*c*) Ceuta, "Arch. der Ohr." Vol. i., p. 107.
(*d*) Magnus, "Arch. der Ohr." Vol. v., p. 127.

which transmitted them through the tube to the ear of the patient.

Politzer (*a*) thought that by using materials absolutely identical to make an entire series of tuning-forks whose constituent parts should have the same form and the same weight we might obtain a sound the same for all. The acoumeters of Politzer vibrate, in fact, in unison. They are composed of a small metal cylinder encased in india-rubber, which allows us to examine the mode of transmission of sound by the cranial bones; the intruments sound "do," and the harmonics which accompany the fundamental are so feeble that they have no influence on the appreciation of the hearing power. Politzer thinks that by the aid of his acoumeters we might express the degree of hearing by a fraction the denominator of which would be equal to the normal hearing power which experience shows to be fifteen metres. The same objection applies to Politzer's acoumeter that it gives only one sound.

Kessel (*b*) had an apparatus constructed, the mechanism of which resembled that of a musical box; it had a cylinder furnished with points which struck against small metallic tongues which, in vibrating, gave a scale of sounds equal to that of the sounds of the human voice. The transmission of the sound was made to the ear by an india-rubber tube, and through the cranial bones by the aid of a metal shank. This instrument is not easily managed, and is only of use in the physician's consulting-room. Its author states that he obtained with it very exact indications.

We find in the Memoir of M. Guerder an analysis of Blake's (*c*) method. Its object was not to measure auditory acuteness, but to determine the part played by the nervous apparatus, and that appertaining to the apparatus of transmission. Blake made use of König's vibrating rods. The difference of the perceptive power between a sound of 100,000 vibrations and more always perceived by the normal ear, and the sound heard, gives the measure of the obstacles presented by the middle ear to the transmission of very high musical sounds. An elevation or a depression indicates increase or diminution of the obstruction in the apparatus of transmission.

Latterly it has been proposed to utilise the microphone for determining the degree of hearing power. Electric currents have been employed more and more feeble in order to arrive at the limit of auditory perception. By previously determining the normal condition we arrive at an appreciation of the degree of impairment of hearing. This very ingenious method belongs more to the physicist's laboratory than the physician's consulting-room. The appreciation of deafness from a clinical point of view, does not require such precise instruments. A similar objection may be made to this as to others, that it acts only in one way, and consequently is useless for appreciating the aptitude of the ear for certain sounds, whilst others of equal intensity give no sensation.

Such are the principal apparatus which have been constructed for the appreciation of auditory sensibility. The problem is a very difficult one, but we must recognise that the question is not yet certainly solved.

It is very necessary in seeking the causes of deafness to ascertain whether the obstacle is situated in the conducting or the perceiving apparatus.

Capdeville concludes that, first, whenever the watch is heard better on the cranium than at a distance of 30 centimetres, and *à fortiori*, when at a less distance, we have to do with an affection of the conducting apparatus. Secondly, whenever the watch is as badly heard on the cranium at 30 centimetres, or is not heard at either of these two points, we have to do with an affection of the deep parts—viz., the internal ear, the auditory nerve, or the nerve centres.

Some deaf people affirm that they hear much better in a noise than in quiet. Von Troltsch (*loc cit.*, p. 259) thinks that this is an illusion, and believes it is due to the fact that, in a noise we raise our voices; that, on the other hand, the deaf person, accustomed to give great attention, profits more easily by a conversation which we do not listen to. He reports, nevertheless, the case observed by Willis of a man who could only make his wife hear him whilst a servant was beating a drum. He also relates the case of a shoemaker, reported by Fielitz, who could only hear whilst beating his leather with a mallet.

To be continued.

Department of Lunacy.

FRACTURED RIBS IN THE INSANE.

In the Annual Report of the South Yorkshire Asylum reference is made to the case of Benjamin Harrison, which was the subject of a question by Mr. Mundella—now Vice-President of the Council—in last Parliament, and regarding which a special inquiry was held by the Commissioners in Lunacy under the direction of the Home Secretary. This man died in the asylum, and at the post-mortem examination of his body, and not sooner, it was discovered that he had in his life-time, and in the asylum, sustained a fracture of the sternum and three ribs. The investigations which have been held by the medical superintendent, the visiting magistrate, and the Commissioners in Lunacy, have not thrown much additional light upon the matter, nor guided to any safe conclusion as to the manner in which these serious injuries occurred. The Commissioners think they may possibly have been produced at an accident, which the deceased met with on the 22nd of June; but as no description of this accident is given, we are unable to say what value attaches to their supposition, the force of which is considerably weakened by a reference in their Report to another fall, which the deceased sustained in a struggle with an attendant. Several of the conclusions at which the Commissioners arrive are far from satisfactory. They say, for instance, that the fractures accelerated, but there is no proof that they caused, his death, which resulted from inflammation of the lungs, which suggests the observation that it would take a good deal of evidence to convince a medical tribunal that death from inflammation of the lungs in a man, with fracture of the sternum and three ribs, was not in direct causal connection with the injuries. Again, the Commissioners remark that the general treatment of the patient while in the asylum was as good as it could be in a large public asylum, when a special attendant in each single room for every restless case is an impossibility; which provokes the criticism, that if a broken breast-bone and three broken ribs be compatible with good treatment, it would be desirable to know what bad treatment amounts to. If in a general hospital a patient after an operation got up in his delirium, tore off his bandages and bled to death, a coroner's jury would, probably, not think it a sufficient answer to a charge of negligence, to be told that in a large public hospital it was impossible to provide a special nurse for each bed. The rejoinder to such a statement would be that it was quite unnecessary to have a special nurse to each bed, and that a staff of one nurse to every six or eight beds would be quite adequate to provide special nursing for each case requiring it. And so in an asylum, there is, can be, no justification for saying that a special attendant is necessary in each single room. A staff of one attendant to every six or eight patients will make it quite practicable to give constant and special supervision to each restless case—the restless cases being always but a small percentage of the total number of patients under treatment. But whatever the staff needful for the purpose may be, this much is certain, that restless patients in asylums whose habits place their lives in jeopardy must have special and unremitting supervision. Humanity demands no less; and asylums will become but costly encumbrances if they cannot ensure personal safety.

The nature of the case of Benjamin Harrison is not indicated, but it is clear that he was a recent admission, and it is therefore probable that he was labouring under some form of mania, or under the excitement of general paralysis or organic disease of the nerve centres. In the latter case it is not un-

likely that his bones were preternaturally brittle, and we are surprised that this fact is not alluded to in the Commissioners' Reports. It is indisputable that the nutrition of bones and joints depends on the anterior grey matter of the cord, and that disease in that region retards the growth of the bones. In posterior sclerosis, as is well known, a painless joint affection, with friability of bones, comes on late in the disease. If this condition existed in Benjamin Harrison it would account for very disastrous results from a comparatively trifling accident.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

The Annual Congress of this Association was held on the 30th July at the Royal College of Physicians of London, under the presidency of Mr. Mould, Medical Superintendent of the Manchester Royal Lunatic Hospital. There was a very full attendance of members from all parts of the United Kingdom. At the morning sitting a hearty vote of thanks was accorded to Dr. Lush, the retiring president, and the usual routine business was transacted. In the afternoon the President read a carefully-prepared and exhaustive address, introducing among other topics for discussion the question of providing detached cottage and villa residences for lunatics apart from the asylum proper, and Dr. Boyd read a paper upon "The Simplification of Admission Formalities." The members dined together in the evening at Willis's Rooms, where they were joined by the Earl of Shaftesbury, Mr. J. T. Hibbert, M.P., and other distinguished guests. Lord Shaftesbury's health having been enthusiastically drunk, his lordship in feeling terms, expressed the great pleasure which it gave him to meet a body of medical and scientific gentlemen of whose services he could speak with the greatest gratitude. Referring to the length of time during which he had been connected with lunacy work, he favourably contrasted the present state of things, both in public and private asylums, with that existing in former years; and alluded to the conscientious manner in which medical practitioners had discharged the duties imposed upon them by the Lunacy Acts, as proved by the evidence adduced before the late Parliamentary Committee, which showed that 185,000 certificates had been issued and persons shut up upon these certificates, and though the Committee sat for six months, yet they did not discover a single instance in which the patients had been shut up without good and sufficient reason. The present tendency (one to be guarded against in the public interest) was to let out everybody who was shut up, and henceforward to shut up nobody at all. It was to be hoped that when measures of lunacy reform were decided upon nothing would be done which would throw unnecessary impediments in the way of early treatment by a mistaken delicacy in regard to the "liberty of the subject." The two great principles to be maintained were a thoroughly efficient, permanent, and independent body of visitors; and every facility, under proper control, for early treatment. The toast of "The House of Commons" was responded to by Mr. Hibbert, M.P.

Mr. J. Rumboll King, M.R.C.S., of Melksham, Wilts, was last week elected a Fellow of the Royal College of Surgeons of England; his membership dates back to 1842.

New York gives the present extraordinary death-rate of 61 per 1,000 of its population; a mortality far exceeding that of such notoriously unhealthy cities as Alexandria, St Petersburg, and Berlin.

The Mineral Waters of Europe.

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS, FOR THE GUIDANCE OF THE PROFESSION AND THE PUBLIC.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C., President of the Pharmaceutical Society of Ireland, &c.

WITH NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond., Lecturer on Materia Medica and Therapeutics at the London Hospital.

(*Continued from page* 91.)

In our previous article we cursorily referred to the composition of the blood by stating that if mineral waters were used constantly at the table their constituents should bear a certain relation to the ash of the blood. This fact has been made use of on more than one occasion amongst the numerous puffs and advertisements put forward by the proprietors of mineral waters, and although like every other theory or proposition of this kind, it is frequently carried to an absurd extent, an abnormal amount, or any abnormal ingredient would be no recommendation to the extensive use of a water for table purposes. Owing to the laws of exosmosis and endosmosis the salts in the blood never undergo any more than a very temporary change in mineral composition, but we can readily perceive that where a copious and constant inroad of fluids highly charged with easily diffusible salts takes place into the stomach—from physical laws alone a certain and unnecessary strain is put upon the animal economy, which must be objectionable. Chloride of sodium and the alkaline chlorides are the most diffusible of all salts, and therefore, from this reason may be considered in reasonable quantities not to be injurious. The alkaline sulphates are not so diffusible, and this probably will account for their more energetic purgative properties.

In the writers' opinion the chlorides of the alkaline earths should never amount to anything very considerable. In excessive quantities some writers on therapeutics are of opinion that these salts interfere with the digestive functions, but on chemical grounds alone we are dealing with bases which, presented in their more soluble condition, have a tendency to form more insoluble compounds, which may give rise to difficulties in the emunctory organs if used in a superabundant quantity over that necessary for bone deposition. The physicians may, however, see cases where such a condition might be desirable. In reference to the analogy desirable between waters for drinking purposes, and blood, we will briefly detail the composition of the fluid. According to Schmidt, 1,000 parts of man's blood contains 513 parts of moist corpuscles, and 486·98 of serum, both rich in salts. The mineral matter of the corpuscles amount to 81·2 per cent., whilst that of the serum is 85·5 per cent. The potassium salts seem to accumulate in the first, whilst in the serum the potassium and sodium salts seem about

equally divided. According to the latest researches of A. Jarisch, 1877, the following are the normal mineral constituents of blood. The acidulous radicals are as follows :—

Phosphoric ($P_2 O_5$) . .	8·61
Sulphuric (SO_3) . . .	11·44
Chlorine (Cl.) . . .	28·63

The writer will add to this list fluorine, which he believes is always present, and must be considered a normal constituent, just as it is of bone. The bases are :—

Sodium ($Na_2 O$) . . .	26·06
Potash ($K_2 O$)	22·92
Lime (Ca O)	1·24
Magnesia (Mg O) . . .	0·52
Ferric Oxide ($Fe_2 O_3$) . .	7·03

Lead and copper have been stated as being present in the blood, but they are simply accidental ingredients just as lithium which appears in the blood after a course of lithia water.

We now come to waters, which are special in their action from containing special ingredients in sufficient quantities to produce marked reactions.

Arsenious acid is one of the ingredients which gives any special therapeutic qualities to mineral waters, more particularly as the dose is small. The mineral waters containing arsenic are, as a rule, even more energetic than a granular dose of arsenious acid *per se* would be. Some of these arsenical waters are said to contain 28 mm. per litre.

Lithia waters are also used to great advantage in special disorders of the urinary organs. Lithium has been found to be an ingredient in an immense number of the alkaline waters, while previous to the introduction of the spectroscope had not been found to give any reactions indicating the presence of that metal. We do not, however, mean by lithia waters such waters as these. Some of the lithia waters contain six to eight grains per pint, and exert very marked chemical reaction. Bromine and sodium are frequently found in mineral waters in considerable quantity.

The deaths referred to diarrhœa in the large towns last week, which had steadily increased from 51 to 337 in the six preceeding weeks, further rose to 577 last week ; they were equal to an annual rate of 5·0 per 1,000 in London, but in the other large towns it did not exceed 3·1.

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Sheffield 15, Bristol 15, Bradford 16, Edinburgh 17, Glasgow 18, Nottingham 20, Sunderland 20, Hull 20, Wolverhampton 20, Plymouth 20, Portsmouth 21, Birmingham 21, Newcastle-upon-Tyne 21, Salford 22, Leeds 22, Leicester 23, Norwich 24, Oldham 24, Manchester 25, London 25, Dublin 28, Liverpool 28, and the highest rate 34 in Brighton.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, AUGUST 11, 1880.

SIR WILLIAM GULL AND THE LATE GUY'S SCANDAL.

Of all the possible outcomes of the miserable indiscretion marking the mismanagement of Guy's Hospital during the past nine months, not one is more lamentable or more to be regretted than the episode which gives the recent trial and conviction of a nurse its chief professional interest. The senior consulting-physician, Sir William Gull, has, in a manner that seems incapable of defence, publicly impugned the propriety of a diagnosis delivered by a brother officer, and in open court, with the knowledge that his words would go forth to the world, has chosen to express an implied slur on the capacity of a physician, whose proud distinction it is to rank as one of the very few men associated in honourable brotherhood with the greatest light of modern physiology. Dr. Pavy's reputation as a physiologist and a diagnostician will bear favourable comparison with that of any practitioner of the present day, and for him to be forced into a defence of his deductions is, at first sight, an incredible supposition. That this course alone remains to him is, however, now certain, since Sir William Gull has taken upon himself, in an important case, to repeat the tactics through which he came into notoriety at the time of the late Emperor

Napoleon's death. It will be remembered that he then supplemented the admirable and exhaustive report of the post-mortem examination performed by Sir James Paget, Sir Henry Thompson, and Dr. Sanderson, with what he termed a *personal opinion*, in which he dissented from the views expressed by this eminent trio on a purely surgical case. *Nemo omnibus horis sapit*, and possibly this opposition of a single *medical* authority on a matter of surgery has been long ago repented of. In the last instance of Sir William Gull's interposition, however, there is almost less excuse than was apparent in the former case. Briefly, the facts are these :—Dr. Pavy was, during the time the woman Morgan was a patient in Guy's Hospital, in constant attendance on her, and after careful and repeated examination, had diagnosed tubercular disease of the lungs. The symptoms were not severe, and for a time the patient progressed favourably. Suddenly, however, other and alarming symptoms set in, and tubercle was manifested in the brain, the progress of the case hastening rapidly to a fatal termination. In his evidence at the trial, Dr. Pavy unhesitatingly declared his belief that the improper treatment to which the patient had been submitted, at least hastened this result, and re-acted detrimentally by hurrying on the brain disease ; giving in effect an opinion that the cause of death was tubercular meningitis, produced by the nurse's untoward proceedings. Next came Sir William Gull, called as a witness for the defence, who "very much doubted whether the bath accelerated death," and thought "the little rise of temperature four days after the bath showed that had nothing to do with causing the disease of the brain."

With the pathological details of the subject we do not propose to deal at present ; neither is it necessary that we should further speak of the comparative value of Dr. Pavy and Sir William Gull's professional opinions. Dr. Pavy will suffer nothing by being thus brought into conflict with his senior *confrère ;* the merits of each are quite well enough understood in professional circles. But there is one aspect of the question with which we are compelled to deal, and it must be in no hesitating manner. Sir William Gull has been guilty of an unprecedented breach of professional etiquette. However much he felt himself bound to dissent from the views of his colleague, the public press is not the medium through which he ought to give expression to his differences. By thus acting he directly fosters the popular prejudice against medical men, already vastly too general, and which it should be the first care of every practitioner to improve out of existence. Neither is there the excuse to be offered that the lay press presented the only means of publishing adverse opinions. Sir William Gull well knows that the columns of the medical journals are open to any honest and courteous criticism ; and we ourselves would have been ready to give him an opportunity of meeting Dr. Pavy in a fair and honourable encounter. Dr. Pavy, too, we are sure, would have readily agreed to discuss the propriety of his conclusions when appealed to in the only legitimate manner, and thereby might have been produced material of use to professional readers, and helpful to medical science, while at the same time the lay press would not have been presented with gratuitous matter for sensational leaders on the way that doctors differ. Sir William Gull is especially bound to be careful of his utterances ; he occupies a foremost position, in the popular estimation at least, as a physician ; and as a member of the General Medical Council, which is the theoretical guardian of professional interests, it is his duty always to be jealously eager to uphold and preserve professional dignity. He has failed, unwarrantably failed, of his trust ; he has given occasion for a widespread dissatisfaction by creating a feeling of mistrust in the infallibility of medical opinions, which mistrust, however ill-founded, is a fatal bar to the successful practice of medicine among the masses.

Dr. Pavy has pursued the right and proper course in demanding from his aspersor a public retraction of his ill-considered expressions. We would fain hope that this may be forthcoming, and that the further resort to a tribunal of the profession may be rendered unnecessary, by a generous avowal on the part of the senior consulting physician of Guy's Hospital that his judgment was hasty and improper. It is admitted that he had for his guide only the clinical report prepared by the student in charge of the case under Dr. Pavy, and it is impossible that he could from this document obtain that insight into the condition and progress of the patient which Dr. Pavy obtained by constant observation of the symptoms she presented. It cannot be urged that Sir William Gull's opinion is not open to grave suspicion. Theorising, however admirable in some places, is inadmissible where medical practice and treatment are concerned, and it is generous to assume that this truth escaped Sir William Gull while giving evidence at the Old Bailey. We shall look confidently for that full atonement which one professional gentleman has a right to expect from another, who hastily and inconsiderately dissents from a carefully-weighed opinion.

ENTERIC FEVER IN THE ARMY.—II.

In India there are recorded 407 admissions by enteric fever in a strength of 56,109 men, and of those cases 167 fatal ; there were 6,434 cases of simple continued fever and febricula with one death, and one case of typhus, death having occurred in it. Under the head of paroxysmal fevers there was an immense increase as compared with the year 1877, the rate of admission (188 per 1,000 of strength) higher, while the death-rate was more than doubled. In the Bengal Presidency cases of "enteric" fever occurred in every division, and, indeed, at nearly every station. They chiefly occurred in the second and third quarters of the year, which contributed more than three-fourths of all the cases of that disease, but of 166 deaths nearly one-half occurred in men in their first year of Indian service, and 26 in men in their second, or a total of 106 out of 166 deaths recorded among men who were less than two years in the country. Ninety-seven were men of twenty-four years of age and under, and 58 were between the ages of twenty-five and twenty-nine. The circumstance is to be noted, however, that no allusion appears to the precise *standard* taken as constituting the affection, so-called, and Reports before us indicate that such standards were very various indeed. Simple continued fever and febricula increased, but only one

death resulted, namely, under the head of simple continued fever. Paroxysmal fevers also were higher in numbers than in the previous year, except at a few stations. Thirty-two of the fatal cases were returned as by remittent fever, and fifteen as ague. In Madras simple continued fever and febricula were much more prevalent than they had been the previous year; "enteric" fever furnished only 7 admissions and 5 deaths, against 65 admissions and 22 deaths in 1877. A good deal of this decrease was considered to be due to a mere change in nomenclature, diseases returned as enteric fever in 1877 being now classed as simple, continued, and remittent; agues and remittents thus show an increase. In Bombay all kinds of fever were more prevalent than in 1877. There were 47 admissions and 25 deaths by "enteric," the increase as compared with that year being considered as in some measure due to *more accurate diagnosis*, although in what respect does not appear. This fever was most prevalent in the last half of the year.

A special Report by the Surgeon-General of Bengal on the subject of "enteric" fever is given in the same Blue Book. The definition of the disease so named is there expressed thus: "A fever of varying degrees of severity and duration, but invariably lasting beyond a week, with an evening temperature of over 100° Fahr, characterised by a tendency to abdominal symptoms, looseness of the bowels, the appearance of rose-coloured spots in successive crops sparsely spread, and pulmonary complication; the disease is invariably connected with splenic enlargement, an infarction of the Peyerian and solitary and mesenteric glands, and commonly followed by ulceration more or less extensive of the agminate glands." Now, in this description we fail to discover anything of a specific nature or indicating a special cause, such as custom has of late sought to identify, namely, filth, or, indeed, any other phenomena than such as were formerly assigned, and with good reason, to the operation of endemic and climatic influences. According to the Report, "when, however, there are few characteristic symptoms and the period of observation is limited, the disease cannot be diagnosed, its nature can only be surmised." That is, if we understand aright, in the absence of *characteristic* symptoms of a specific disease, the specific name of that very disease, the characteristic symptoms of which are absent, is to be applied. Surely this is seeking after that which is not obvious, and neglecting what is evident. As regards morbid anatomy the observation of Louis is quoted, "to the effect that in this disease it was not necessary to see the whole body, a few inches of intestine is sufficient to identify it." But among the more recent and equally high authorities, some describe the pathology of specific enteric fever as undistinguishable from that of non-specific endemic fevers and other diseases. "By some, all organic or animal, but especially fæcal contamination of air or water is regarded as the cause;" "by others such contamination is regarded" as "but of a very specific kind;' —that is, in India, according to the portion of the Report already quoted, as a cause of a disease, which, when it "cannot be diagnosed, its nature can only be surmised." This being so, may the question not be appropriately asked, what is it exactly that the remarks refer to? According to the Report, "attempts have been made in a loose and indefinite way to indicate alliances between malarious disease and enteric fever." That is, between endemic or climatic fever and the *enteric* or bowel complication which sometimes is also present; but, according to the Report, this *alliance* is in reality "a sign of affinity and material relationship of these diseases," acknowledged even now to exist between them. As to post-mortem appearances "the results derived from a perusal of the Reports furnished to this office, as well as my own personal observations of the cases themselves, leave no doubt, whatever, in my own mind that you can and do meet with numerous instances of *a disease* in this country undistinguishable from what is recognised as enteric fever elsewhere;"—a circumstance acknowledged by the older writers since this century began, and before it. "That the exanthem is wanting in many cases, and diarrhœa in others; that its character as a fever may be modified, and its fatality increased by heat and climate; that the disease may begin suddenly and with symptoms *resembling* ague; that it may indeed follow ague, exhibit a malarious character, or resemble some remittent or tropical form of disease rather rhan enteric fever, is nothing to the purpose." Rather, we would say, is everything to the purpose, and demonstrates that the actual disease to be dealt with is itself "of malarious," that is, climatic nature, it may be with intestinal *complication*. The remark occurs that "the ratio of fever mortality in the gross of past years, if taken in relation to months and weekly arrived regiments, is nearly absolutely identical with that of enteric fever at the present time;" the natural conclusion to be drawn from this being, that except as regards *name*, the actual disease met with is unchanged in its character. "Here, as elsewhere, enteric fever varies in severity, from the abortive and mild type up to the most grave and fatal forms of the disease." So also do the several forms of endemic or climatrical fevers. "The liability to die from enteric fever in the case of the soldier above seven years' service in India being 3·87, as contrasted with 82·44 in the young, and 13·69 in the class resident from five to seven years, reckoning liability at 100." And so it is with respect to all forms of fever in India. "As a rule, enteric fever manifests itself in India at the end of April or beginning of May, frequently appearing at the end of the monsoon season (end of August)." Making every allowance" for a desire to assign some cause or another, without considering its relevancy or adequacy, "medical officers have utterly failed in India to trace out the intimate connection of this disease with filth causes or specific infection." In that case, why do so many observers still continue to cling as it were to such causes, notwithstanding all this? Would not the following paragraph from the same Report rather afford the real and sufficient explanation, namely:—"The marked tendency which *the* disease has shown to appear at certain seasons, April, May, August, and September, as if in response to the action of some seasonable conditions at those times?" An allusion occurs to the probable influence of the water at these seasons. But are not the seasonal conditions themselves sufficient to induce fevers, ardent in the former, more purely malarial in the latter, but in either case becoming *complicated* in particular individuals with infraction of Peyer's glands?

The Report contains this further remark, namely:—"While fully recognising, then, the force of the evidence on which European pathologists dwell in regard to the specific nature of enteric fever, and its connection either with specific or *filth* causes, it is impossible on the other hand to resist the evidence that such causes fail to embrace all the facts observed in this country (India)." Here, we think, lies the main gist of the question as to whether specific, that is, pythogenic fever, does or does not prevail among British troops in India? as also the further question, whether phenomena in life, and appearances after death, similar to those which characterise the specific disease in Europe, occur as a *condition* of, or *complications* in the course of fevers in India due alone to general causes, climatic and endemic in their nature, affecting individuals under particular circumstances of diathesis, age, residence, and habits? At pages 331 and 332 of this Blue Book, notices appear of two prizes to be awarded for the best essays on enteric fever, and we trust the outcome may be a clearer understanding than seems at present to exist with regard to the disease so-named, particularly in its relation to British troops in India.

IRISH POOR-LAW DRUG CONTRACTS.

It is, unfortunately, almost unheard of for a Board of Guardians in Ireland to take sufficient interest in the quality of the medicines supplied to their paupers, that they would think it worth while to make any inquiry on the subject. Imagine a dozen of cotter farmers and small shopkeepers put to adjudicate between a number of tenders for articles which they never saw in their lives, and of the fair price of which they have not the remotest idea, and suppose them having to make their choice without the help even of a printed price list. Of course, and in all reason, they select the cheapest article, or give the contract to the friend they know best. Could they be expected to do otherwise? Then, again, imagine a shopkeeper called upon to supply a quantity of expensive goods to a customer who will never see the articles—would not know what they were if he did see them—had not the least idea of their proper price, and, perhaps, cared very little whether they were good or bad. Of course, and in all reason, the average contractor would supply the cheapest article he could lay his hands on, would manage his tenders so as to get the biggest possible price without losing the contract, and would take good care to keep the customer in the best humour with him and his dealings. Could any ordinary contractor be expected to do otherwise? Now this is exactly the state of affairs as regards the supply of medicines to the Irish poor, and we have already pointed out in detail that from the existence of such a system two results eventually and, as a matter of fact, almost universally accrue. In the first place, the sick poor are cruelly cheated of the medicinal help which they need in time of sickness, and which their doctor fondly imagines that he is giving to them. In many instances the utter uselessness of the pharmaceutic rubbish which is supplied by contractors for their use produces no worse effect than delaying the recovery of the poor man, and pauperising his wife and family. A labourer, for instance, with a bad attack of dysentery, will probably recover some time or other, although the remedies ordered for him may be of no value whatever, but his recovery will take double the time, and involve double the degree of subsequent pauperism which would accrue if genuine reliable medicines were administered. But, in cases of life and death, the substitution of fraudulent drugs for pure ones is worse than roguish, it is murderous. The father of the family, whose life is in the balance, may be saved, if a given effect can be produced upon his disease in a given time, but the effect is *not* produced because the medicine which should produce it is dishonest rubbish, and a life is then and there sacrificed because there exists no means of ensuring the purity of union drugs. Thus much for the effect upon the sick poor. The ratepayer also pays toll to the nefarious system which exists, for while the Guardians gratify themselves with the belief that they have, at least, been economical, the real fact is that they are paying a scandalously exorbitant price for all their ordinary drugs. The trick by which certain drug contractors have managed to grow rich upon the innocence of the guardians is well known. They know that the contract will be given to the tender which has the lowest tot at the bottom of the price column; accordingly, they reduce that tot to the least possible amount by setting down, at an infinitesimal price, all medicines which they are certain will never be ordered, while, at the same time, they put down a monstrous price for all those drugs which are in common use. For instance, they will price atropia at, say 1s. per ounce, though the market price of it is £4, and, in the same column will set down castor oil at 2s. per lb., the fair price for it being 8d. They know that the dispensary doctor will never want more than a few grains of atropia, and that, therefore, they cannot lose much on that item, but he will need gallons of castor oil upon the exorbitant price of which they will make a profit of some hundreds per cent., and thus they can make it appear that they are supplying the medicines at an extremely low price, while they really are mulcting the ratepayers most scandalously.

We have said it is unfortunately almost unheard of for a Board of Guardians to make any inquiry as to the purity of their drugs. The Carrickmacross Guardians have the honour of being the one and only Board which has done so of recent years, and they have brought to light by the agency of Dr. Cameron, the county analyst, the existence of a system of fraud in drug contracts which the initiated have long been aware of, but of which Poor-law Guardians had no thought. The analyst's report we published *in extenso* in our issue of the 21st ult.. Here are a few excerpts:—

"The quinine, so-called, did not contain any quinine at all, but was composed of a substance about one-eighth the price of sulphate of quinine. The tincture of catechu contained about one-half of the amount of extract yielded by properly prepared tincture. The tincture of cinchona was deficient in spirit, and contained about three-fourths the amount of extract which it ought to include. The costly article, saffron, is wholly absent fron it. The etherial tincture of lobelia extract deficient to the extent of about one-fourth the proper quantity; the ether cheap 'methylated.' In the tincture of perchloride of iron there appears to be no spirit of wine at all in it. In the aromatic spirit of ammonia the ammonia is in excess, but the

far more costly aromatic oils are in a great deficiency in this tincture. The aromatic sulphuric acid contains two-thirds only of the amount of sulphuric acid; it contains very little spirit of wine and very little bark."

Let it not be supposed that there is in this any new discovery, or that it is likely to create any official indignation. For years, the prevalence of these practices has been well known to most Poor-law medical officers in Ireland and to the Irish Local Government Board, for the system has been repeatedly exposed and the proofs given in these and other columns. The medical officers have not moved, for it is not any part of their duty to do so, nor have they even the legal proofs necessary to establish their accusation, if they made it. Moreover, the few medical officers who have complained have been uniformly snubbed by the members of their Board of Guardians who were on amicable terms with the prince-contractor in Dublin. An instance of this occurred not long ago, when a medical officer produced a chemical analysis to prove that the sulphur supplied to him for pauper use was more than half plaster of Paris; nevertheless, his remonstrances brought upon him such obloquy that he was glad to withdraw his accusations, and let the matter drop.

The Irish Local Government Board is the public department whose business it is to supervise these drug contracts and to provide a remedy for the system, and it has confessed years ago that it is fully aware of its existence to the extent which we have indicated. Nevertheless, the Local Government Board refuses to stir hand or foot to save the pockets of the ratepayers and the lives of the sick poor. And why? Forsooth, they are in a huff, because, many years ago, an impracticable, inefficient, and unfair proposal made by them to establish a large central drug shop in Dublin, with a handsomely paid official over it, was refused by the guardians throughout Ireland. And for this reason the Irish Local Government Board continues to patronise and protect the perpetration of the chicanery of which we have spoken.

It is very doubtful whether any reform can be hoped for, yet we have thought it our duty to point the moral of Dr. Cameron's report, which we have quoted above, and thus acquit the medical profession in Ireland and ourselves of any hand, act, or part in the perpetuation of the Irish Poor-law drug contract system.

Notes on Current Topics.

The Compulsory Notification and Registration of Acute Infective Diseases.

In pursuance of a resolution unanimously adopted at the last annual meeting of the flourishing Dublin Branch of the British Medical Association, the Council of the Branch has been exerting itself to obtain an expression of opinion in favour of the proposed measure; and a promise of aid and co-operation in its endeavour to secure its advantages for Dublin, from the corporations which represent medicine and surgery in that notoriously unhealthy city, and from the Irish Medical Association, as representative of the several bodies of the profession throughout the country. The Branch Council may congratulate itself on the support it has so far received. Not only have the colleges passed resolutions approving of the principle of the measure, but they also showed the importance which they conceived belongs to the matter by both appointing committees to report upon it. Thus the all-important questions of detail in the carrying out of the Local Act which it would be necessary to obtain, received an amount of consideration from those most qualified to form valuable opinion upon the matter which otherwise it would have been most difficult to obtain. The following is the resolution which was passed by the Royal College of Surgeons:—

That this College recognises the great desirability of registration of infectious diseases, and would approve of any measure which would make efficient provision for such registration without interfering with the confidential relation of the physician to his patient, or imposing upon him a responsibility inconsistent with his professional practice. That the College considers that in any legislative proposition the onus of reporting to the sanitary authority ought to devolve upon the responsible occupier of the house in which the disease occurs.

The resolution adopted by the King and Queen's College of Physicians states that:—

The College approved the principle of compulsory notification of infective diseases, provided the duty of notifying is imposed only on the head of the family or owner of the house in which the disease occurs; and also the principle of registration of infective diseases; and that the College will be glad to assist and co-operate in obtaining the necessary parliamentary powers for securing the advantages that would, in their opinion, result from the attainment of an efficient system of notification and registration based on the lines indicated.

And at a special meeting of the Council of the Irish Medical Association the following important resolutions were unanimously adopted:—

1. That this Association fully recognises the advantages of an efficient system of early and compulsory notification and subsequent registration of acute infective disease.
2. That, as regards notification of infective disease, the duty of the medical attendant shall consist alone in informing the head of the family or the occupier of the infected house what the nature of the disease is, to the best of his knowledge and belief, and that it is infectious.
3. That the duty of notifying the presence of infection to the sanitary authority shall devolve solely upon the head of the family or the occupier of the infected house.
4. That in the case of the illness of a person who has not been attended by any medical practitioner, it shall be incumbent on the head of the family or occupier of the house to notify to the sanitary authority the presence of infective disease in his house as soon as he becomes aware of its nature, and, if in doubt, to obtain the opinion of a duly registered medical practitioner thereupon.
5. That, as regards the registration of infective disease, the Association is emphatically of opinion that the duty of such registration should not be compulsorily imposed upon the registrar of births and deaths.
6. That, in the case of large urban districts, it seems desirable that the registration should be effected by means of a special organisation in connection with the general register office.
7. That, for every case of infective disease registered by a duly registered medical practitioner, a fee of not less than half-a-crown shall be paid to said medical practitioner.

The Public Health Committee of the Corporation, and the Executive Committee of the Dublin Sanitary Association, have also pronounced in favour of the principle of the notification of infective disease.

Dr. Tanner's Fast.

THE forty days' advertisement on which Dr. Tanner entered has been concluded, and the only possible result of the performance has been attained—that, namely, of converting its hero into the best-known individual of the day. Whether the newspaper notoriety secured by Dr. Tanner will be a sufficient recompense for the discomfort he is said to have experienced is for himself to determine; but that his exhibition will be productive of any gain to science is not worthy of serious consideration. The conditions of the sensation have, from the first, been preventive of anything except ephemeral fame to the faster, the evident efforts after effect precluding anything like a scientific investigation in connection with the affair. It is, perhaps, a little unkind of the newspaper writers, who ought to be grateful to the subject of so much "copy," to detract from the marvel of the fast by raking up the records of ancient imposture, as has been so plenteously done; but it is impossible to regard the whole thing in a light more serious than that of a monstrous show. Spite of Dr. Hammond's testimony, and that of those who with him afford certificates of genuineness, we are content on this side of the Atlantic to cherish the possibility that time will produce the exposure of little details likely to lessen the opinion now held in certain quarters of Dr. Tanner's wonderful staying powers. If the ostensible purpose of the fast had been an increase of scientific knowledge, why, it must be asked, were not the surroundings of the experimentalist made such as would favour the record of the results, and assist the ascertainment of fresh particulars concerning the progress of starvation. The accompaniments of gallery for walking in, hall for exhibition, drives amid admiring crowds, levees, and daily performances, all savour too much of the Barnum business to deserve the attention of the inquiring physician. It is a good thing the fast is over, for during the continuance of it an unhealthy feeling has been engendered in the public mind, and its suppression is desirable.

The Army and Navy Medical Services.

WITH the much-needed reforms have come in plenty of candidates for Army medical appointments. Last week eighty-six candidates for the Army sent in their names for the examination which commences at Burlington House this week, beside thirty-five for the Indian Medical Service. Candidates were also invited for the Navy, but only eight names have been sent in. My lords of the Admiralty will have to swallow the bitter pill which their colleagues of the War Office so long objected to, but ultimately took, ere they will get the junior members of our profession to rush into their arms. The *Broad Arrow* understands that one of the appointments at the headquarters of the Army Medical Department will shortly become vacant by the departure of Surgeon-General W. Munro, C.B., on foreign service. Deputy Surgeon-General Woolfryes, C.B., lately appointed principal medical officer of the Southern District, is likely to succeed him. Surgeon-Major S. E. Maunsell, with Surgeons Cowen and Clark, embarked at Portsmouth last week in the *Orontes*. Surgeon-Major Wade is detailed for medical charge of the troops leaving England on the 6th in H.M. Indian troopship *Euphrates*, with Surgeons Baker and Michael as assistants. Surgeons-Major Murtagh and Jones, and Surgeon Flood are held in readiness to proceed to India to augment Medical Department there. Forty of the newly-joined surgeons who have completed the Netley course, and also undergone instruction in ambulance and stretcher drill at Aldershot, have been warned to hold themselves in readiness to embark for the East at short notice.

Presentation to Dr. Neild, of Melbourne.

THE medical profession in Melbourne have joined in the presentation of a splendid gold cup to Dr. Neild, on his retirement from the Secretariat of the Victoria Medical Society and the editorship of the *Australian Medical Journal*, which he had held for seventeen years. The address presented to Dr. Neild expressed in deservedly warm terms the gratitude and affection towards him entertained by his professional brethren in the Colony. The cup weighed nearly twenty-four ounces of 18-carat gold. The design was purely Australian, the ornamentation consisting of a double stem and foliage of the Darwinia Neildiana, a rare and beautiful species of plant found in Western Australia.

Medical Officers in Afghanistan.

"BULLS' RUN" says, in *The World*, "it only remains to immortalise in some befitting manner the three field-officers and *five doctors* who were the first to reach Candahar from the field of Kushk-i-Nakhud. The medical profession, moreover, should specially set its mark of approbation on these five active brethren." And so doubtless the medical profession will do, should it hereafter unfortunately turn out that such "a mark" is deserved; in the meantime, however, it is but bare justice to "the five doctors" concerned, that before passing a verdict on their conduct we should hear what they have to say for themselves.

A New Hotel for Army and Navy Medical Officers.

EVERY enterprise is now floated on the co-operative principle, whether it be a monetary speculation, a philanthropic idea, or one for personal advantages in the shape of home necessaries at cost price, or club and hotel comforts, minus the extravagance usually attendant upon such affairs. The medical club started in London some few years since was not a success; its range was too limited, and the co-operative principle was not then in vogue. An hotel and club has now been started upon modern principles to be called the "Army and Navy Hotel," which shall embrace the advantages of club life, with the residential accommodation of hotels at greatly reduced charges. To medical officers in the Services this idea, if successfully carried out, will be of immense advantage. From the nature of their calling, change is very frequent, and to Indian officers particularly, a metropolitan centre of this kind, where they can put up on arrival, and meet their brother officers during leave of absence, will be much appreciated. We understand that a site has been secured in Victoria Street, opposite the Army and Navy Stores, and that building operations will be commenced forthwith.

British Medical Association.

The meeting of the British Medical Association for 1880, commenced at Cambridge, on Tuesday (yesterday), under the presidency of Professor Humphry. A discussion on the Treatment of Wounds will be part of the proceedings, Professor Lister having agreed to introduce the subject. Sir Henry Thompson will open a discussion on Stricture of the Urethra, and a large number of important and interesting questions are down for debate; among others may be mentioned, the Influence of Alcohol on the Causation of insanity, the Removal of Uterine Tumours by Abdominal Section, the Diseases Communicable to Man from Animals and as Food, and the general working of the Public Health administration of Great Britain and Ireland.

Pathological "Desiderata."

The Pathological Society of London has taken a praiseworthy step in publishing a list of questions requiring investigation in pathology, under the title of *desiderata*. This will be of service to workers who may be anxious to devote their attention to this line of research and in doubt as to what particular subjects may be open for investigation. It will not in any way interfere with independent work, but will probably do much to aid on progress in this particular branch of discovery. The list is a very large one, but it presents only a few of the possible subjects to be followed.

Carbolised Camphor in Diphtheria.

In the treatment of diphtheria Dr. Peraté has for the last two years employed carbolised camphor. He applies it by means of a brush soaked in the following solution: Phenol (carbolic acid), 9 grammes; camphor, 25 grms.; alcohol, 1 gramme; diluted with an equal quantity of almond oil. The applications are made at first every two hours during the day, and every three hours during the night, and the interval between them is gradually increased. The application is made over the whole of the false membrane, and in refractory children the brush is plunged well to the back of the throat. The taste of the mixture is very disagreeable, but patients soon become accustomed to it.

The Treatment of Ozæna.

In a patient affected with a muco-purulent fœtid nasal discharge for a year, Dr. Wolfrau (*Berl. Klin. Wochen.*), employed twice a day aspirations for five minutes at a time of a solution of tannin and glycerine, 2 per cent., preceded by irrigation of the nasal fossæ with a litre of a solution of sea salt. After a fortnight he had recourse to a solution of acetate of alumina, at first of ½ per cent., and then 1 per cent. The nasal secretion diminished in abundance and fœtidity; then the number of douches and nasal inhalations was reduced. After six weeks the patient was cured of his ozæna which had not reappeared in two years.

Salicylated Camphor in Phagedænic Ulceration.

In the treatment of this form of ulceration Dr. Lajoue (*La France Medicale*) employs an ointment composed as follows:—Camphor, 10 grammes; salicylic acid, 10 grammes. These are mixed and then there is added, Alcohol (at 90° C.), 10 drops; vaseline, 10 grammes; paraffine, 25 grammes. This makes a consistent ointment which is put upon the wounds.

Peptogenic Elixir.

In cases of dyspepsia where the indications are to favour the secretion of gastric juice, and to introduce peptogenic substances into the stomach, Dr. Dujardin-Beaumetz employs an elixir the formula of which (*La France Medicale*) is as follows:—Dextrine, 10 parts; rum, 20 parts; syrup, 60; water, 120. This elixir has a very agreeable taste, and is of service in the cure of atonic and putrid dyspepsia.

The Treatment of Sweating in Phthisis.

In the treatment of the nocturnal perspiration of phthisis Dr. Kohnhorn (*Le Progrès Medical*), uses a powder which is employed in the Prussian army in sweating of the feet. The formula of this preparation is as follows:—Salicylic acid, 3 grammes; starch powder, 10 grammes; talc, 87 grammes. The body, and especially the chest, should be sprinkled with the powder.

Dr. Tanner completed his forty days' fast on Saturday, and confesses that he is little the worse for the experiment; he ate ravenously of meat and fruit immediately the self-imposed task was completed.

The nurse who was tried last week at the Central Criminal Court for the manslaughter of a patient in Guy's Hospital, has been committed to prison for three months.

On Thursday last, Mrs. Rutley, who stood charged under remand for illegally keeping three lunatics for profit, was brought up and convicted for the offence, judgment being postponed till Saturday, when she was fined £50.

We understand with very great pleasure, that the Home Secretary's ill-advised scheme for abolishing cumulative penalties under the Vaccination Act, which has raised such a storm of disapprobation, is to be abandoned.

Under the will of Mr. J. Macgregor Mackay, of Brighton, the Edinburgh Royal Infirmary has received £1,000. The Paisley Infirmary has received £1,000 under the will of Miss Jessie Gordon, and the Huddersfield Infirmary £1,000 as a donation from Mr. Cuttell, of Long Walls.

Dr. Berkart, of London, has been elected a corresponding member of the Société des Sciences Médicales et Naturelles de Bruxelles, in recognition of his scientific studies of the pathology and treatment of asthma and other subjects.

Henry Morton, a chemist, of the Broadway, Deptford, has been fined £5 at the Greenwich Police Court

for selling a tincture of quinine which was adulterated in such a manner as seriously to injure its properties as a medicine. We were sorry to see a medical man giving evidence in this case to shield the defendant from the consequences of his fraudulent practice.

The death-rate from the seven principal zymotic diseases per 1,000 last week in the large towns ranged from 0·8 and 1·7 in Bradford and Newcastle-upon-Tyne, to 10·9 and 13·6 in Norwich and Brighton. Scarlet fever showed the largest proportional fatality in Norwich and Salford. Small-pox caused 4 more deaths in London, 7 in Dublin, but not one in any of the other large towns.

We are happy to note that Dr. Alexander Flood, medical officer of the Holywell dispensary district of the Enniskillen Union, has been presented with a valuable piece of plate and an illuminated address by his patients and friends, on resigning his appointment through ill-health, after thirty-four years' service. The address and reply will be found in our advertisement columns.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 18, Bombay 27, Madras 37; Paris 29; Geneva 22; Brussels 24; Amsterdam 23, Rotterdam 19, The Hague 21; Copenhagen 31; Stockholm 37; Christiania 26; St. Petersburgh 42; Berlin 47, Hamburg 26, Dresden 28, Munich 36; Vienna 27, Buda-Pesth 34; Naples 37; Alexandria 51; New York 61, Brooklyn 43, Philadelphia 27, and Baltimore 29 per 1,000 of the population.

The coming meeting of the British Association for the Advancement of Science will commence on Wednesday, August 25, 1880, under the presidency of Andrew C. Ramsay, Esq., LL.D., F.R.S., V.P.G.S., Director-General of the Geological Survey. W. Morgan, Esq., Ph.D., F.C.S. (Swansea), and James Strick, Esq. (Swansea), Local Secretaries.

The reception room at Swansea will be opened on Monday, August 23, at 1 p.m., for the issue of tickets to members, associates, and ladies, and for supplying information to strangers on their arrival. Without a proper ticket, obtained as above, no person is admitted to any of the meetings. The first general meeting will be held on Wednesday, August 25, at 8 p.m., when the president-elect will assume the presidency and deliver an address. On Thursday evening, August 26th, at 8 p.m., a soirée. On Friday evening, August 27th, at 8.30 p.m., a discourse by Professor W. Boyd Dawkins, M.A., F.R.S., on "Primeval Man." On Monday evening, August 30th, at 8.30 p.m., a discourse by Francis Galton, Esq., M.A., F.R.S., on "Mental Imagery." On Tuesday evening, August 31st, at 8 p.m., a soirée. On Wednesday, September 1st, the concluding general meeting will be held at 2.30 p.m. On Saturday, August 28th, Henry Seebohm, Esq., F.Z.S., will deliver a lecture to the operative classes on "The North-East Passage." The sections are:—A. Mathematical and Physical Science; B. Chemical Science; C. Geology; D. Biology; E. Geography; F. Economic Science and Statistics; G. Mechanical Science. Excursions to places of interest in the neighbourhood of Swansea will be made on Saturday, August 28th, and Thursday, September 2.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Health of Edinburgh.—For the week ending with Saturday, the 31st ult., the mortality of Edinburgh fell from 81 to 67, and the death-rate was 16 per 1,000. Only one death from fever was reported in the New Town, and only one from diphtheria in the southern suburbs.

Edinburgh University.—Graduation Ceremonial.—The annual graduation in medicine in connection with the University of Edinburgh took place on the 2nd inst. in the Assembly Hall. There was, as usual, a large attendance. The Lord Justice General presided. Professor Turner presented the graduates. Twenty-seven students received the degree of M.D. under the new statutes, and 1 under the old; 124 received the degree of M.B. and C.M., 6 the degree of M.B., and 1 the degree of C.M. Three of those who received the degrees of M.B. and C.M. are clergymen. The Cameron prize was presented to Professor William Roberts, Owens College, Manchester, for his discovery of a good artificial means of partially digesting food. Professor Rutherford addressed the graduates, and chose for his subject that of medical reform. His address, from the academic point of view, must be characterised as an able and ingenious one. The history of medical science, he said, was that of prolonged struggle against serious difficulties. Looking back on the history of medical education in the country, they found that its present advanced standpoint had been mainly owing to the influence of the Universities, and most of all to those of Scotland. And it was the University of Edinburgh that had taken the lead. One great reason of the success of the Scotch Universities was undoubtedly this, that unlike the University of London they were not merely examining, but also teaching bodies. They did not distract the student by exacting a high standard of attainments without, first of all, providing the means of education whereby he might raise himself to that standard. The result had not been to keep the standards of education and examination low, but, on the contrary, the examination standard had been gradually raised without difficulty, owing to the antecedent elevation of the teaching standard. And thus it has come about that a more elaborate system of practical tests is applied in examinations here than elsewhere in the country. In Scotland 70 per cent. of the medical practitioners are University graduates, while in England the proportion is only 25 per cent. Professor Rutherford, in conclusion, criticised the recent scheme of examination proposed by the London reformers, saying he hoped they would hear no more of it. If it had been sanctioned its effect would have been to lower the standard of examination. Universities and medical corporations should, he considered, be kept entirely apart. There might be, however, instead of the proposed triportal system, two sets of portals through which the medical profession might be entered; a set of university portals and a set of corporation portals, the latter consisting of the conjoined corporations of London, those of Dublin, and those of Edinburgh and Glasgow; half of the examiners being nominated by the corporations, and the other half subject to the approval of the Medical Council.

Correspondence.

THE STATE OF THE DENTISTS' REGISTER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question of the expurgation of the Dentists' Register has of late been the subject of much comment, especially on the part of the British Dental Association.

The subject has heretofore been approached in what may be termed a purely dental aspect, ignoring the fact that there are important collateral issues affecting the rights and privileges of the medical profession which ought to receive some attention, even from a Council either wanting in the knowledge of the extent of its powers or deficient in the courage of asserting them.

I am not even assuming that the gentlemen who registered as dentists were in any case not in the *bonâ fide* practice of their speciality at the time of the passing of the Act, but I nevertheless consider that the ingenious coupling of the practice of medicine and surgery with dentistry by gentlemen who hold no medical or surgical qualification whatever is a fraud alike on the public and profession.

On analysing the Dentists' Register the following facts speak for themselves: Out of a total of 34 who announce their connection with medicine and surgery there are 15 (nearly half) whose names do not appear on the Medical Register.

The public are induced to believe that five follow dentistry in connection with the practice of medicine and surgery; two with surgery only; one with pharmacy and surgery; and seven with medicine only; and what is still worse, some of the gentlemen leave their certificates lying on their desks, framed, &c., evidently to show their patients official evidence that they do follow dentistry in connection with surgery, &c.

Trusting that the parties who are responsible for the Dentists' Act will in justice devote their energies to the removal of a most anomalous state of things,

I am, Sir, yours, &c.,

FRANK THORPE PORTER, F.R.C.S.I.

15 Upper Merrion Street, Dublin,
July 22, 1880.

[Undoubtedly the same legal decision which declares that a dentist cannot be registered as practising in connection with pharmacy unless he be legally a pharmaceutist, applies to one who registers as practising dentistry "in conjunction with medicine or surgery" if he be not a registrable medical practitioner. Therefore we hold that the whole fifteen names given to us by Dr. Porter are illegally on the Dental Register, and must be expunged by the Medical Council.—ED. M. P. & C.]

REGISTRATION OF DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the number of the *Medical Press and Circular* bearing date 14th July, this year 1880, it is stated that at a recent meeting of the King and Queen's College of Physicians in Ireland, it was resolved, "That the College approve the principle of compulsory notification of infectious diseases, provided only that the duty of notifying is imposed on the head of the family or owner of the house in which the disease occurs; and also the principle of registration of infectious diseases as an owner of house property." Might I ask, in the name of common sense, how can a house owner know of the existence of disease being in the house as stated in said resolution? I would also put the question to the Irish Medical Association for a reply.

I am, Sir, your obedient servant,

July 20, 1880. SELWOR.

[It is part of the proposition that the medical attendant shall inform the head of the family as soon as he recognises the disease, of its nature, either by a printed notice or verbally.—ED. M. P. & C.]

Literary Notes and Gossip.

THE Council of the Statistical Society acknowledge the receipt of the Essays on the "Oriental Plague," in competition for the Howard Medal of 1880, under the following mottoes: "Διοσδὲ Τελείετο Βουλή;" "Mente Manuque;" "Sur Espérance;" "Quid non pro Patria;" and "Volans arsit arundo."

* * *

THE title of the essay for the Howard Medal of 1881 (Bronze with £20 added), is "On the Jail Fever, from the Earliest Black Assize, to the last recorded Outbreak in Recent Times."

* * *

AMONG the five successful competitors in the scriptural essays recently announced, were two members of the profession—Dr. Redman, of Lincoln, and Dr. Meymott, of Ludlow.

* * *

THE suggestion that Professor Mommsen, the celebrated *savant*, whose library was burnt some few days since, should be supplied with a new one at the national expense meets with approval in Berlin, and it seems likely that it will be carried out. The offer of assistance from Oxford has, however, been declined by the learned Professor.

* * *

THE *Globe* says:—Messrs. Baillière, Tindall, and Cox have just published a remarkable work, called 'A Chronology of Medicine, Ancient, Mediæval, and Modern,' edited by Mr. John Morgan Richards. It is not merely an essay on medicine, but contains many extraordinary things in the sections relating to the State papers and old advertisements. On page 171 is a document in which a code of sanitary laws is laid down very creditable to the physicians of two centuries ago." We hope to notice this book fully a little later on.

* * *

IN a previous column of "Literary Notes and Gossip," we mentioned dubiously, an invention called the "Diaphote," by Dr. Jechs, of Bethlehem, United States, by the aid of which the possibility of recognising persons thousands of miles distant by means of reflective mirrors and telegraphy, was said to be an accomplished fact. Upon the face of it a hoax was obvious, although it was gravely copied into hundreds of journals. We now learn from our well-informed contemporary, *The Boston Medical Journal*, that the supposed discovery originated in a travesty on a scientific paper, and that in its transference through various media, both title and authorship were eventually so metamorphosed that the author could scarcely recognise his own child.

* * *

THE discoverer of the elegant figures named after him Lissajous' figures, is dead. The deceased physicist was professor at Toulouse, and leaves a large circle of friends to mourn his loss.

* * *

DR. GEORGE M. BEARD publishes in New York a small pamphlet entitled, "What Constitutes a Discovery in Science," and which comprises a portion of the preface to the second edition of his work on Neurasthenia. The little work is amusing, if nothing more, and in the final paragraph bursts out into frenzied eloquence of expression that must be read to be appreciated. Whether Dr. Beard has answered the question he proposes to reply to, may be, without very great impropriety, doubted.

* * *

MESSRS. JOHN HEYWOOD, of Manchester, have issued in a neat and inexpensive form the eleventh series of "Science Lectures for the People," delivered at Manchester during the winter, 1879-80. Mr. Arthur Russell Wallace, Mr. B. Waterhouse Hawkins, Canon Tristram, and Captain Abney, contribute to the volume, which is edited by Prof. Roscoe, and fully maintain the high reputation of the lectures already published.

* * *

THE *Therapeutic Gazette* often contains articles well worth reading, and recent numbers are in every way as deserving of praise as the earlier ones. A paper on the "Causation of Epidemic Disease," by Augustus Kaiser, M.A., M.D., is a scholarly and clearly reasoned review of the known conditions surrounding the outbreaks of epidemics. It is an admirable brief summary of the history of epidemiology.

* * *

MEN rarely arrive at dignity without having to pay for it sooner or later. The latest victim of this is a distinguished member of our profession, in the person of Sir George Burrows, Bart., Physician in Ordinary to Her Majesty, who has

been flattered by the dedication of a washing-book bearing his name, by Mrs. Strange Butson, and "through him to the whole medical profession." Does the authoress insinuate that Sir George and the rest of the profession neither wash themselves nor understand when their shirts are clean or dirty? The book certainly has the merit of novelty; on the outside cover are a couple of shirts, a towel, mop, scrubbing brushes, water cans, and a pail; whilst inside three different coloured papers are used "to illustrate the three formations—granite, old red sand, and silurian," though what geological formations have to do with the "art of washing" the authoress does not condescend to discuss.

* * *

Dr. Bourneville, the well-known editor of *Le Progrès Medical*, has brought out a capital *resumé* of the progress of medical science in 1879, under the title of "L'Annee Medicale." This is the second year of its publication, and the work is well done. It differs in many respects from Braithwaite's "Retrospect," although it resembles it in others. Instead of consisting of isolated articles taken bodily from the medical journals, each branch of medical science, anatomy, physiology, medicine, surgery, therapeutics, &c., is treated of in a connected article in which the results arrived at by the various investigators who have published works or articles during the year, are given in a succinct and condensed form. The work is an exceedingly useful book of reference, and its value is greatly enhanced by the very complete analytical index with which it is furnished. We hope Dr. Bourneville will find sufficient encouragement to continue the publication annually for many years to come.

* * *

Messrs. Cassell continue the serial issue of their "Family Physician." As we have before remarked we are opposed to all works on so-called "Domestic Medicine," but the public will endeavour (sometimes to their cost) to learn doctoring, and such being the case, it is better they should be supplied with trustworthy rather than untrustworthy information. The work, the seventh part of which is now before us, maintains the good character which we were able to accord to the first part.

* * *

Under the auspices of the New York Academy of Sciences a series of six popular scientific lectures have recently been delivered before the Young Men's Christian Association of that city. Amongst them was one by Dr. L. Elsberg, the well-known American laryngologist, on "The Throat and its Functions." Dr. Elsberg has printed and published this lecture, and it is a very useful and accurate description of the subject of which it treats. A knowledge of the anatomy and physiology of the channels through which we take in both the food and the breath of life must be of value to all, and Dr. Elsberg places it before us in clear and untechnical language, elucidating his meaning by excellent illustrations.

* * *

During the month of July there were published four hundred and eighty-one works in medicine, surgery, and allied sciences throughout the world. The subjects were—Anatomy, six; physiology, nine; anthropology, eight; chemistry, four; medicine (including general diseases, fevers, &c.), forty-seven; insanity and diseases of the nervous system, thirty-two; the circulatory and respiratory systems, nineteen; urinary and generative systems, nineteen; materia medica and therapeutics, twenty-one; surgery, fifty-one; gynæcology and obstetrics, thirty-eight; hygiene, forty-nine; dermatology, ten; ophthalmology, twenty-six; otology and laryngology, eight; dentistry, three; state medicine, six; medical education, seven; and medical jurisprudence and toxicology, seven. The foregoing statistics do not include pamphlets, of which there were at least three times the number published.

* * *

At Highgate Cemetery, a few days since, funeral honours were paid by a considerable number of the medical and literary professions to the mortal remains of one in whose company, during a too brief lifetime, so many delighted. At the early age of forty-five Dr. Arnold Beer has passed away. Although a German by birth, having been born at Frankfort, his early years were spent chiefly in England. In the first instance, he devoted himself to the study of medicine, and was the author of several scientific medical works which attracted considerable attention. At an early age, however, he gave up the pursuit of medicine as a profession, and occupied himself with purely literary studies. He was well-known as an author in Germany, and had it not been for his premature death he might have been expected to attain high eminence as a man of letters.

* * *

New Books and New Editions. — The following have been received for review since the publication of our last list, June 30th:—"The Half-Yearly Retrospect of Medicine," edited by Drs. W. and J. Braithwaite. "Traité d'Anesthésie Chirurgicale," par le Dr. Rottenstein. "Practical Lithotomy and Lithotrity," by Sir Henry Thompson, F.R.C.S. (3rd Edit.) "Medical Education and Practice," by H. J. Hardwicke, M.D. "La Syphilis son Histoire et son Traitement," par le Dr. J. Tartenson. "The Dissector's Guide," by D. J. Cunningham, M.D. "On Aneurism," by Richard Barwell, F.R.C.S. "A Dictionary of German Terms Used in Medicine," by G. R. Cutter, M.D. "Contributions to Orthopædic Surgery," by J. C. Hutchison, M.D. "The Throat and its Functions," by Louis Elsberg, M.D. "The Archives of Laryngology: a Chronology of Medicine," by J. Morgan Richards.

* * *

Pamphlets, Annual Reports, Etc.—The following have been received since June 30th:—"Fifth Annual Report of the Darenth Schools and Asylums for Invalids." "Associated Homes," by E. V. Neale. "Annals of the Anatomical and Surgical Society of Brooklyn." "Special Dangers to Health in Large Towns," by J. Tatham, M.D. "The Diagnosis of Granular Kidney," by R. Saundby, M.D. "Colpocystotomy by Electro-Cautery," by J. Byrne, M.D. "Contributions to Gynæcology," by J. Byrne, M.D. "Unipolar Stimulation in Physiology," by A. de Watteville. "Health Economy," by Francis Vacher. "On the Educational Treatment of Incurably Deaf Children," by W. B. Dalby, F.R.C.S. "Forty-fifth Annual Report of the British Medical Benevolent Fund." "Can Disease Protect Health," by E. Robinson, M.R.C.S. "Hydro-Incubation in Theory and Practice." "What Constitutes a Discovery in Science?" "The Problems of Insanity," by G. M. Beard, M.D.

Special.

INDIAN MEDICAL ITEMS.

The Grievances of Medical Officers.—According to a telegram dated Calcutta, 8th instant, "it is stated that the Marquis of Ripon, Viceroy of India, intends to institute a careful inquiry into the grievances of the Indian Medical Service." We offer our hearty congratulations to the members of that service on this good news.

The Candahar Forces. — Deputy Surgeon-General J. O'Nial, A.M.D., is principal medical officer of the 1st division of the Candahar field force, under command of Lieutenant-General Primrose, C.S.I. Surgeon-Major L. S. Bruce, I.M.D., is principal medical officer of the 2nd or Reserve division of the same force under the command of Major-General Phayre, C.B.

Medical Officers in General Burrow's Forces.—The following medical officers are reported to have reached Candahar safely from the defeat of General Burrows by Ayoob Khan, namely, Surgeon-Major C. Harvey, Surgeon Burrows, Eaton, and Dane.

The Indian Medical Service.—Surgeon G. A. Cones is appointed to the medical charge of 22nd Bengal N.I., Surgeon-Major R. F. Hutchinson remains at Mussoorie on sick leave till October 28th. Surgeon-Major A. J. Ferguson has leave to England for six months on urgent private affairs. Surgeon E. J. Brander proceeds to Murree on sick leave till October 28th. Surgeon W. L. Gibbins has leave to England for eight months. Surgeon-Major H. G. Archdale officiates as civil surgeon of Dera Ghazi Khan, and Surgeon J. E. C. Ferris as civil surgeon of Kohat. Surgeon-Major J. McN. Donnelly, of the Madras Service has obtained leave of absence on sick certificate for two years. The arrival of Surgeons-Major J. Reed and C. Cooper is reported.

Cinchona Consumption.—Mr. Ferguson, in his Ceylon Directory, estimates the total consumption of cinchona bark for the world at 12,624,000 lbs. A writer in the *Columbo Observer* says:—"I do not think I am over-estimating the number of cinchonas that will be planted in 1880 throughout the Island at 20,000,000; allow 5,000,000 for failures, and add 5,000,000 for plants planted in previous years and now

alive, and it will give you 20,000,000 cinchona trees, which in five years will yield, either by taking strips and mossing, or by the shaving process, about 10,000,000 lbs of dry bark a year." Mr Ferguson estimates the production of cinchona bark for the world at 13,471,000 lbs., of which Ceylon is put down for 150,000 lbs., but when, remarks the correspondent referred to, "it produces 10,000,000 lbs., as I believe it will in 1885, the total production of the world will exceed the demand of 1876-78 by 10,847,000 lbs. The question therefore arises, will the demand for cinchona bark in 1885 equal the supply, or will the bark become unsaleable except at unremunerative prices?"

INDIAN MEDICAL SERVICE PASS LIST.—The following list of candidates for commissions as surgeons in Her Majesty's Indian Medical Service who were successful at both the London and Netley examinations has been forwarded to us from the India Office :—

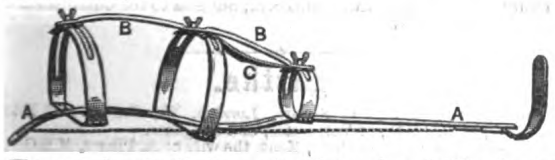
HIP SPLINT.

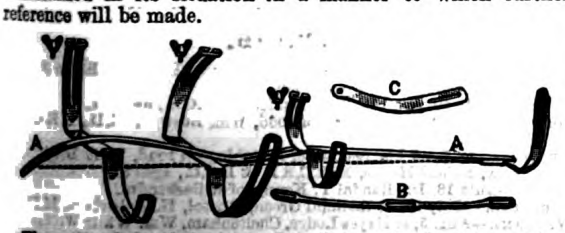
Designed by E. O. DAY,

Medical Officer to the Royal Hospital for Children and Women, Waterloo Bridge Road.

THE splint consists essentially of the three rods marked A, B, and C. The foundation rod A extends behind the whole length of the body. At the upper end it is recurved so that its extremity descends below the line, dotted in the diagram standing from A to A. Hence it will be seen that the patient cannot be disturbed without lifting the body entirely from the bed. There is, therefore, no liability to bend the hip-joint, which in that position is effectually supported on the splint.



The second rod, B, is employed to give rigidity in any position that may be found suitable to the bands which encircle the body. These bands are flattened on the posterior aspect and thus prevent isolation of the whole system—body and splint together—while the possibility of giving them a fixed position relatively to the body enables us to provide against rotation of the one upon the other. The desideratum of an immovable attitude is thus secured and the rod A is maintained in its situation in a manner to which further reference will be made.



There remains only one motion to be restricted, *i.e.*, rotation of the pelvis upon the head of the femur induced by elevation of the pelvis from the bed. For this purpose a flexible rod C has been introduced. This can be made to take the curve of the groin with the greatest nicety, and without putting pressure upon any part renders it quite impracticable to execute any movement that might raise the body away from the foundation rod A.

Parallelism of the lower extremities is very effectually secured by this splint. Any asymmetry that may exist in the earlier stages of disease, when pain is acute, may be corrected in the usual way by attaching a weight and so drawing down the limb by slow traction. Parallelism having been established, is maintained not alone by the bands which encircle the body fixing thorax, pelvis, and spine in invariable relations, *inter se*, but also by the rod C upon the limb, which, by preventing flexion and adduction, abolishes the conditions that induce rotation of the pelvis and curvature of the spine.

Nor must the importance of a secondary effect obtained by means of the abdominal band and the particular figure given to it and its colleague be here overlooked. The efficiency of the foundation rod A to prevent movements of the limb depends almost entirely upon its being maintained behind the limb, exactly in the plane of its rotation. It is the vice of many hip splints that they are apt to slip to one side or other of the limb, and consequently to afford play for considerable movement.

Summarised, the points in favour of this splint are :—

That it is less cumbersome than most others. It thoroughly immobilises the limb. It maintains parallelism. It dispenses with all bandaging.

Medical News.

Royal College of Physicians and Surgeons, Edinburgh.—*Double Qualification.*—The following gentlemen passed their first professional examination during the July sittings of the examiners :—

Appleton, E., Stockton-on-Tees
Batten, H. A. W., London
Berry, J. J., Pendlebury
Brewer, Charles Samuel, Liverpool
Burdon, John, Cleadon
Carmody, Michael, Limerick
Carr, Henry Wilkinson, Sussex
Clayton, A. J., Yorkshire
Crossley, Charles, Leicester
Gynne, J. H., Staffordshire
German, F. F., Fenton, Staffordre
Hanson, E. R., Cornwall
Jephcott, R. W., Warwickshire
Johnson, S. E., Newp't, Isle of W.
Legat, H. T., South Shields
Matheson, Hugh Bullen, Liverpool
McMichael, John, Dublin
Perkins, A. F. Cwm Aman, S. W.
Roberts, R. G., Liverpool
St. George, Capel Baldwin, Dublin
Stephens, D. H., North Shields
Shortridge, Herbert, Yorkshire
Spence, W. J., Darlington
Taylor, J. J., Newcastleton
Tisdall, J. J., Redmonstown, Irel.
Wise, T. A., Isle of Man
Watteville, W. F. R. de, Berne

And the following gentlemen passed their final examination in July and August and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh :—

Addison, C. J., Weymouth
Anderson, Robert, Newry
Bradshaw, J. C., Staffordshire
Boyd, R. J., Wells, Somerset
Bryce, P. H., Mt. Pleasant, Canada
Birkett, Henry John, Whitehaven
Crossley, Charles, Leicester
Cuscaden, George, Wexford
Cooke, L., Sutton in Ashfield
Close, J. A., Croydon, Ontario
Clark, Robert, Yorkshire
Chambers, J. T., County Tyrone
Dalston, G. W., London
Doughty, William, Canonbie
Duncan, A. L., Banffshire
Dunn, W. A., Manchester
English, Joseph, County Antrim
Fowler, Richard, Dublin
Fonceca, R. J. T., Madras
Graham, John Campbell, Bonn
Hall, J., Rokeel, Ireland
Harkness, Alexander, Belfast
Jones, R. O., Carnarvonshire
Kerrigan, O. P., Mullingar
Kelly, M. D., Limerick
Leitch, James, Inverary
Lowry, John Henry, County Down
Liston, Henry, Edinburgh
Macintyre, A., Stirlingshire
McNicoll, John, Liverpool
McWilliam, John, London, Ontario
Mitchell, Adam Garrett, Limerick
Marsh, J. H., Farnworth, Bolton
Martin, J. McCardie, C. Londond'y
Moloney, Denis, Duagh, Kerry
McDonogh, Patrick, Clapham
Osburne, John, Cork
Oatley, John, County Cork
Parette, James, Perth
Pope, Robert, Newbigging, India
Richardson, F. L. C., Rhayader
Rodgers, J. W., Nezapatam, India
Smailes, F. W., Pickering
Scanlan, A. E., Chester
Stuart, Charles, Berwickshire
Swan, Edward Goffe, St. Helena
Taylor, R. G., Grahamesto'n, C. C.
Torbitt, Charles, Warwickshire
Wardle, M. A., Stratford-le-Bow
Ward, Herbert, Yorkshire
Watt, William John, Beltast
Watson, A. A., Galashiels
Whitham, Alfred, Haworth
Whitaker, J. M., Dublin

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their first professional examination during the recent sittings of the examiners :—

Andrews, James, Glasgow
Ellis, John William, Doncaster
Moglan, Michael Joseph, Galway

The following gentlemen passed their final examination and were admitted licentiates of the College :—

Barlow, Thomas Carey, Dalston
Barny, Richard Winter, Dublin
Ellis, John William, Doncaster
Palmer, B. A. County Armagh
Pestonji, Bejanji, Bombay
Williams, Isaac, Cerrig-y-Druidion

The following gentlemen passed their first professional examination for the Licence in Dental Surgery of the College :—

Fraser, Hugh, Largs
Tracey, H. W., Ipswich

James Stewart Durward, Edinburgh, passed his final examination, and was admitted a Licentiate in Dental Surgery.

University of London.—Entire First M.B. Examination. Pass list.

FIRST DIVISION.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

PATER.—Most of the English schools open on October 1st, the majority of the Irish and Scotch schools are later. Full instructions, with courses, expenses, &c., will be given in our "Student's Number" in September. Few of the prospectuses have as yet been received, consequently changes may be made which would invalidate any advice we might give you thus early.

MR. WILSON.—The school referred to is probably about the least expensive in London.

A FOURTH YEAR'S MAN should read up Gant's or Bryant's "Surgery" and Foster's "Physiology."

DR. J. E. R.—A point of etiquette about which there is scarcely room for question. Our correspondent should send his neighbour the little vest pocket companion entitled "Rules of Medical Etiquette," published at one shilling by Baillière, Tindall, & Cox.

DR. FOX.—The pass-list appeared in our last number.

AUTHOR.—See "Literary Notes" present number; the subject was also referred to in our issue for June 28th.

AN ANCIENT MEDICAL CHARITY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—On the boundary line of Rochester and Chatham is situated the Chapel of St. Bartholomew, together with the ruins of the Hospital for Lepers, which was attached to it. These formed one institution founded by Gundulph in 1078. The leper's home is replaced by our excellent general hospital, and we are endeavouring to restore the venerable Norman Chapel, now over 800 years old, the sole remaining link which binds us to what is, I believe, *the oldest medical charity in England.*

Plans were furnished by the late Sir Gilbert Scott, who speaks of the chapel as a "precious archæological and historical relic, the preservation of which is of the utmost importance." The sum of £600 is still required to complete this good work. Will you allow me to appeal to your readers for help on medical, ecclesiastical, archæological, and architectural grounds?

I will gladly furnish the fullest particulars to any one who may be disposed to assist, and I hope that some of those whom God has prospered in their profession may be willing to give of their substance for the preservation of His house.

Yours, &c.,

JOHN BAILEY, B.A., LL.B.,
Chaplain of the Chapel and Hospital of St. Bartholomew, Rochester.

DR. D. C. B.—The journal has been forwarded to the address stated. If it lead to the suppression of the quack Dr. (!) Smith's advertisement in that newspaper so much the better. Our exposures have had this effect in several instances.

VACANCIES.

Gloucester County Asylum.—Junior Assistant Medical Officer. Salary, £100, with board and lodgings. Applications to the Committee of Visitors on or before Aug. 13.

Kent and Canterbury Hospital.—Surgeon. Applications to the Secretary not later than Aug. 13.

North Eastern Hospital for Children.—House Surgeon. Salary, £70, with board and lodgings. Also a Registrar. Salary, £50. Applications to the Secretary not later than Sept. 1.

APPOINTMENTS.

BENHAM, F. L., M.B., Resident Clinical Assistant to the West Riding Asylum, Wakefield.

GEOGHEGAN, E. G., M.D., Assistant Medical Officer to Portsmouth Borough Asylum.

GEORGE, G. A., L.R.C.P.Ed., M.R.C.S., Medical Officer for the Dorchester District and Workhouse of the Dorchester Union.

GOYDER, C. M., M.R.C.S.E., L.R.C.P.L., Senior House Surgeon to the Newcastle-on-Tyne Infirmary.

JONES, T., M.B., F.R.C.S.E., Consulting Surgeon to the Children's Hospital, Pendlebury.

KEELAN, P., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Callon Dispensary, Ardee Union.

LITTLE, J., M.D., M.Ch., Junior House Surgeon to the Wigan Infirmary.

MCARDLE, Mr. J. S., Resident Surgeon to St. Vincent's Hospital, Dublin.

MCDONNELL, E. P., L.R.C.S.I., Resident Surgeon to Gervis Street Hospital, Dublin.

MANBY, F. E., F.R.C.S.E., Honorary Surgeon to the Wolverhampton and Staffordshire Hospital.

MONTFORT, A. H., M.D., M.Ch., Assistant House Surgeon and Dispenser to the Kent and Canterbury Hospital.

NEWNHAM, C. A., M.R.C.S.E., Consulting Surgeon to the Wolverhampton and Staffordshire General Hospital.

O'CONNOR, C. J., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Clane Dispensary, Naas Union.

O'DEA, P. St. L., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Ennistymon Dispensary, Ennistymon Union.

WRIGHT, G. A., M.B., B.A., F.R.C.S.E., Surgeon to the Children's Hospital, Pendlebury.

Births.

BRUCE.—Aug. 2, at Norland Square, London, W., the wife of Peter Bruce, M.R.C.S.E., of Valparaiso, of a daughter.

PIGGOT.—Aug. 4, at Beckenham, Kent, the wife of A. Piggot, M.R.C.S., L.R.C.P., of a son.

Marriages.

BARNES—HUGHES.—Aug. 4, at Llandovery, Robert Barnes, M.D., of 15 Harley Street, London, to Alice Maria Hughes, daughter of the late William Garnon Hughes, J.P., of Glancothy, Carmarthenshire.

SPURGIN—PARKINSON.—Aug. 5, at St. Mary's, Islington, Thos. Spurgin, M.R.C.S., L.R.C.P.E., of Moreton Ongar, Essex, to Anne Andrew, eldest daughter of Samuel Parkinson, of Canonbury, London.

Deaths.

ALLEN.—Aug. 1, at Budleigh Salterton, Devon, Elizabeth Blane Allen, widow of the late Matthew Allen, M.D.

BIDDEN.—July 29, at Hull, R. C. Bidden, M.R.C.S., aged 71.

BOSWELL.—July 20, at Upper Norwood, Wm. Boswell, M.D., F.R.C.S., of Quebec.

HEELIS.—Aug. 1, at his residence, Blatchington road, West Brighton, Sussex, Robert Heelis, M.R.C.S.E. & L.A.C., aged 81.

KENNY.—July 18, Dr. Randal Y. Kenny, of Killeshandra.

ROBERTSON.—July 24, at Redland Green, Bristol, H. Robertson, M.D.

WILLIAMS.—Aug. 5, at Hayes Lodge, Cheltenham, Wm. White Williams, M.D., F.R.C.P., late Medical Superintendent of the Gloucester County Lunatic Asylum.

Abstract

OF THE

PRESIDENTIAL ADDRESS

DELIVERED AT THE

MEETING OF THE BRITISH MEDICAL ASSOCIATION.

By Professor HUMPHRY, M.D. Cantab., F.R.C.S. Eng.,
Surgeon to Addenbrooke's Hospital, Cambridge.

AFTER a few words of welcome Dr. HUMPHRY proceeded :—

Gentlemen, as you wander through the sacred groves and the time-honoured buildings of this many-sided and deeply interesting place, feel, I pray you, that you are not merely welcomed by those who are now permitted bodily to receive you, but realise to yourselves also that you are in the presence chamber of the mighty dead, that—

"Where'er you tread 'tis haunted, holy ground";

that every turn you take is hallowed by the impress of a Newton or a Bacon, of a Cranmer, a Latimer, or a Ridley, of a Spencer, a Milton, or a Byron, of a Porson or a Macaulay, of a Wordsworth or a Wilberforce, of a Harvey, a Glisson or a Heberden, of a Whewell, a Sedgwick or a Selwyn; feel that the very stones are reminders of their presence, and cry out in their honour, and speak to you, and welcome you in their names. Those worthies loved the men of work and the men of worth. As such you claim fellowship with them, and a right in the places where their memories live, as well as a heritage in the institutions which the liberality of our forefathers has bequeathed.

And, yet, as you passed the threshold of this place, was not each one troubled with the insuppressible questions, What in these long years, with this might of intellect, and with its forcing power of wealth, has Cambridge done for medicine? Has there not, through the whole period of academic history, been enacted a divorce, a most unnatural divorce, as it were, between body and mind, between, that is to say, the nurturers of the one and the cultivators of the other? While Bellini in Pisa, Hoffmann and Stahl in Halle, Boerhaave in Leyden, Van Swieten and De Haen in Vienna, Sauvages and Astruc in Montpellier, Mondini and Valsalva in Bologna, Montagni, Morgagni, Fabricius ab Aquapendente, Prosper Albinus and Vesalius in Padua, Fallopius in Venice, Cullen, Brown, and the Munros in Edinburgh, were adding to, and rolling on, the great stone of medical science, and were drawing pupils from all parts of the world, and were shedding an unfading lustre upon their several universities, how came it that students of medicine could look to no master teacher here, and that medical science could date no advance from Cambridge?

Such barrenness in a great faculty was certainly never intended, was not contemplated, by our founders and first legislators. In the earliest college statutes, permission or direction is given to some of the members to pursue the study of medicine. In the scheme for the university, which was in the main taken from the University of Paris, the faculty of medicine was placed on a par with those of theology and law, and the provisions for teaching and graduating in the three faculties were alike. In the professiorial foundations by Henry VIII, by which the professorial system, as distinguished from the preceding method of teaching by regents, bachelors, and doctors, was inaugurated, medicine shared in common with the other faculties. The Regius Professorship of Physic received at that time an endowment and a status similar to those of theology and law; and in the additions to the professoriate which were subsequently made from time to time, the medical sciences have had their fair share.

To these great and interesting questions, as to many others on subjects no less largely affecting the welfare and destiny of man, the answers are not direct and easy, and are to be found, if at all, only by a careful study of the history of the past.

In the early part of the thirteenth century when the gathering of pupils and teachers here seems first to have come under the legal direction of the Sovereign, when students were arriving from Paris, and Cambridge was beginning to organise itself upon the model of that great university, the study of medicine, which meant little more than a culling of the views of Aristotle and Galen, obscured and misrepresented in their transmission through Arabian translations, was much confined to Salerno, as law was at Bologna, and theology to Paris. Learning, though reviving from the depression which almost amounted to extinction, was at a low ebb, especially on the north of the Alps, and was chiefly in the hands of the clergy, who thought secular knowledge to be unworthy of the attention of men whose minds should be engrossed with the great subjects of the, as they imagined then impending, dissolution of the universe; and natural science, where it had any existence, was still poisoned by the follies and mysteries of alchemy, which had not yet given way before the genius of Roger Bacon. This country which, five centuries earlier, before the desolating inroad of the Danes, had taken the lead in Europe, and had sent from its schools of York and Canter-

bury men who, under the far-reaching wisdom of Charlemagne, drew the first outlines of the French and German universities, was now in the background, at anyrate it could boast of no superiority. Those who would make any progress in medicine were compelled to resort to foreign universities, as did Caius and Harvey to Padua and Bologna, in which latter place Vesalius, after the long and almost unbroken interval which had elapsed from the time of Galen, was venturing to dissect the human body, and was followed by Eustachius and Fallopius. Caius, Harvey, and others returned to England; but none of them came back to Cambridge to found a school of medicine here, or to add the lustre of their names and the vigour of their intellects to such school as there was here, for there must have been some sort of medical teaching in the university. There were then, as there ever have been, greater pecuniary and courtly attractions elsewhere. They proceeded on their return from abroad, to practise their profession, or prosecute their studies, in various parts of England. Caius, it is true, after practising in Shrewsbury and Norwich, was not unmindful to his college, which he refounded and governed till shortly before his death in 1573, though apparently he still resided chiefly in London. In his foundation he was not forgetful of the interests of medicine; and he showed his sense of the importance of anatomy, acquired doubtless during his residence with Vesalius at Padua, by obtaining, in the sixth year of Queen Elizabeth, a license that his college might, for ever, yearly take the bodies of two malefactors and dissect them without the control of any person. Whether Harvey, when at Caius, may have derived from this any stimulus to his researches, or, indeed, whether the privilege was ever acted on, I cannot tell. But that there was no great accession to medical study and teaching in Cambridge we may infer from the fact that Glisson, who held the Regius Professorship of Physic for forty years, from 1637 to 1677, was a resident in London.

Ere this, events had occurred which seriously influenced the relations of London, Oxford, and Cambridge to the study and science of medicine. The highly learned Linacre, the great promotor, indeed renovator of learning, more particularly of Greek, in this country, beholding with concern that the practice of medicine was chiefly engrossed by illiterate monks and empirics, endeavoured to strike at the root of this evil by obtaining from Henry VIII, in 1518, letters patent for the foundation of his College of Physicians, with the privilege of licensing practitioners throughout the kingdom. The graduates of Oxford and Cambridge were exempted, forasmuch as, by virtue of their degrees, they were independent of the College, except within its precincts. Linacre lived to carry out and superintend his plan. Lectures were delivered at the College, and London thus became a centre of teaching, as well as of licensing the practitioners of medicine and surgery; and a new and formidable rival to Oxford and Cambridge was raised in the growing capital of the kingdom. But Linacre, who had been a student and doctor of Oxford, and an incorporated graduate of Cambridge, was not unmindful of the two universities. He showed his anxiety for their welfare, and his desire to promote the study of medicine in them, by bequests for the foundation of lectureships. Unfortunately, owing to the mismanagement of his trustees, these intentions were never carried out. The proceeds of his property assigned for the purpose, were, in great measure, lost; and the residue was diverted by private influence, at Oxford, to Merton College, and, at Cambridge, to St. John's College.

To proceed, however, with my brief narrative. During the seventeenth and eighteenth centuries, the influence of Aristotle gave way to that of Bacon and Newton, and the system of the university verged more and more to the exclusive pursuits of mathematics and natural philosophy. Classics, at length, contrived to force a recognition. The rich prizes given exclusively for these two school subjects extended the study of them into too late a p riod of life, attached an undue importance to them, dwarfed all other subjects, both at the schools and at the universities, deterred those students from coming to Cambridge who had not a taste or capacity for them, or who had not sufficient means of prolonging their school education, and, to say nothing of the religious restrictions, had well-nigh divested the university of the character of a national institution, and of its claim to public sympathy and regard.

Slowly and somewhat tremblingly the advancing wave of broader educational view came on, and showed its first influence, in 1851, in the foundation of the natural and moral sciences triposes. These were followed in succession by the theological, the law, the historical, the Semitic, and the Indian languages triposes. The subjects of these triposes are growing in estimation and in favour; the provision for teaching them is, year by year, more carefully and liberally made; and rewards for the successful study of them are more willingly granted.

Why not a medical tripos also? I may suppose you inquiring. I can only answer by expressing the hope that, when you next come to Cambridge, you may be relieved from the necessity of asking the question.

At the same time that a wider range was given to the studies of the place, the rigid and inelastic statutes of Elizabeth, which had for three centuries held the university with an iron grip, have been relaxed under the heat of public opinion—that sterling friend to Cambridge—and have given way to a freer constitutional code, which has afforded scope to, and thrown into strong relief, the naturally liberal spirit of the place.

That a great future, most potent for good, in connection with medicine, is open to Cambridge I cannot doubt. The opportunity is before her—not, I grant, to make amends for past shortcomings. That can never be done. The past can no more be made amends for than it can be recalled. The debt of lost time and occasion cannot be repaid, except in so far as regret for the omissions of the past may stimulate to better effort in the future. The opportunity is open, not simply to influence the few, but to leaven the large masses of the profession. The opportunity lies in a progressive advance and expansion of the teaching, under which I include examining; for examining should ever be regarded as the handmaid and most important adjunct of teaching. In proportion as Cambridge avails herself of this opportunity, and in that proportion only, will her influence upon medicine be great and good. Her social advantages are much and rightly valued; her literary renown is high; her academic prestige is great; her buildings are inspiring; her history is long and noble; but it is not upon these, but upon the high character of her teaching, that her future must stand.

Cambridge must give that kind of teaching which will engender broader and clearer appreciation of principles, which will render the study of medicine a medium for the cultivation of intellect, as well as a means of passing into a profession and earning a livelihood. It must show the scientific to be the natural and necessary adjunct to the practical, and must weave the two together into the woof of a high educational system. In no other branch of knowledge are the two so naturally and so entirely conjoined; in no other is there so much that is calculated to give strength and balance to the thinking and the observing faculties; none in which mental and bodily effort is more required and more telling. There is no one, therefore, which is more worthy of university culture, or which would more truly profit by it. May we not also say that, of all the physical sciences, medicine is the most difficult, the most important, the highest? What problems can be so hard of solution as those which relate to the aberrations of the most exquisite of organisms—the organism in which the properties of matter reach their maximum of variety, of complexity, of exquisiteness of combination and action—the organism in which they have their outcome in an association with the marvellous attributes of responsibily and intellectual process. These problems of healthy and morbid action transcend all known methods of calculation; and, as is too commonly found under such circumstances, are liable to fall under the range of dæmonology and quackery—at any rate, to come within the scope of that mysterious and unfathomable *ignotum* which transcends the *magnificum*. The very difficulty of the problems causes them to be ignored or overlooked. Men scarcely venture, or are able, even from a distance, to contemplate them, and therefore have a tendency to leap over them on to conclusions, without calculating the data which brought them there.

And is such a subject, so fitted to evoke and invigorate the mental powers, and upon the successful prosecution of which the future destiny and welfare of our nation and of our race so much depend, not to receive its fair recognition in this great seat of learning? Is Cambridge to stand aside for the future, as she has too much done in the past, and keep aloof from the task of generating and wielding this potent force? Is this important member of the body politic of the University to be suffered to go unnourished and untended, to the great detriment of the whole? My own experience tells me that such is by no means now, whatever it may have been, the feeling or desire of the members of the University. Certainly it

cannot be the feeling or desire of the members of the British Medical Association.

It is in the preliminary subjects of medical study, those which form the subjects of the earlier medical examinations, in addition to the broad ground of general education, that Cambridge will find her most appropriate sphere. The feeling is growing that these subjects would, for many reasons, be best taught apart from the great centres of clinical instruction; and it would be an enormous benefit to the cause of medical education to secure a thoroughly good teaching in these subjects upon the basis of sound general education. This, I am sure, lies at the root of the improvement we are all desirous to effect in our profession; and it is in this work more especially that Cambridge may and ought to play an important and conspicuous part in the future.

In evidence of this, I may refer to the buildings—the New Museums—which will be occupied by you during the meeting, and in which a suspension of our ordinary teaching work is necessitated for the accommodation and carrying on of your sections. And here I would observe, you must not suppose that "vacation" in Cambridge implies cessation of work. On the contrary, the practical classes are, for the most part, continued during a considerable period of the vacation; and some of the best work of this kind is then carried on, because the regular courses of lectures being discontinued, and the lecture rooms yielding to the laboratories and the hospital, the student can devote his attention more uninterruptedly to the last. This week's holiday is in compliment to, rather is enforced by, your presence. I make that remark because it is right you should know that the vacation is not now, whatever it may have been in times past, a vacant period in Cambridge; and because, unless you bear in mind that this week's interruption of medical study is an exceptional condition for which you are responsible, you would carry away a wrong impression of our vacation life. The erection of the buildings to which I have referred, with the laboratories, lecture-rooms, and dissecting-rooms, for experimental physics, botany, mineralogy, mechanism, optics, zoology and comparative anatomy, and physiology, and the provision of a staff of professors and demonstrators, and the better provision for chemistry and human anatomy, are an evidence of the impulse which the teaching of these sciences has lately received in the University, and are the forerunners of further building upon the same plot, by which it is hoped that, ere long, geology will find a suitable dwelling, worthy of the name, and in honour of the memory, of Sedgwick, and that a much needed expansion of the chemical and medical schools will be effected. I speak of a much needed expansion of the medical school—and those of you who are anxious to inform yourselves respecting this will have the opportunity of learning for yourselves that, though physiology is thoroughly equipped—as thoroughly as in any European school, and though the means of teaching and studying chemistry and anatomy have been augmented to meet the requirements of growing classes of students, yet in both of these a further improvement might with advantage be made. A well endowed professorship of pathology is about to be instituted, and a suitable pathological laboratory must be added. A fully complete curriculum Cambridge does not profess; but a sound scientific and practical teaching in the first two stages of medical education—in physics and chemistry; in anatomy and physiology, vegetable, comparative, and human—and a careful clinical training at the hospital, associated with pathology and therapeutics, are quite within our scope, and the teaching in them, I trust, will continue to be carried on with yearly increasing efficiency to a yearly increasing number of students.

This vast Association, one of the greatest guilds that ever existed, is an enormous power, and it has its own proportionate responsibilities. The united force of eight thousand members ought to roll on the great stone of science, and impel the wave of good feeling to the gradual wearing away of false dogmas, and the still falser notions of conflicting interests, and should stimulate to that unity of purpose and oneness of brotherhood, associated with oneness in a great and holy work, which are among the high ideals of Christianity. It is by greatness of result, rather than by greatness of numbers, that we must be judged. The greater the force, the greater the waste, unless it be well applied.

But one work—a work that especially appertains to the Association, the work of collective action, of the pull altogether of eight thousand members of the profession, I mean the work of cumulative observation, or accumulated data—has been too little attempted; or, if attempted, has been productive of too little result. I am aware that anything on a large scale of this kind is a serious undertaking, a gigantic enterprise; and I feel it, therefore, to be worthy of this gigantic Association. It is, perhaps, the only work in which all, or a large part, of the members can really and fully participate, and to which each can contribute his mite. It is almost the only way in which questions relating to temperamental, climacteric, and topographical agencies upon disease, and many others can be fully investigated and solved.

In the well stored and well used library of Crosse of Norwich, five and forty years ago, my little services were enlisted in the work of the Association, not so much for any good they did to it, but rather on account of the gain he knew it would be to me to be early trained in the feeling that a higher vocation than that which I might suppose to belong to the student of medicine, was opening upon me in the vocation appertaining to the membership of a great brotherhood, and in the duty devolving upon me as a member of a great profession. It was no small thing to have one's sympathies thus early awakened and directed. To the Association I have adhered ever since, as a means of keeping those sympathies alive; and when the proposal was first made that the present meeting should be held in Cambridge, I felt that we were bound to afford you the opportunity you asked of coming to this much loved place, this fair spot upon which our own lot has fallen.

Original Communications.

ON FEVERS IN INDIA.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to Her Majesty the Queen.

(*Continued from page* 111.)

g. "DR. GORDON had further quoted in support of his views as to the rarity of 'fever' an opinion of a distinguished author which was penned as far back as 1843, since which date that author had, as was well known, not only changed his views, but had accepted the classification of the continued fevers proposed by Stewart and Jenner." Nevertheless, the statement as made holds good in regard to the time stated. In paragraphs 37 and 38 of my second Report I have, as far as I was able, given the views of present authorities on this point, but as extracts from them would be too long for this communication I can only refer you to them. I notice, however, that one of these authorities therein named "regarded the continued fevers of Great Britain as fundamentally the same disease;" while a second, also named, "held that the doctrine that various kinds of continued fever as arising from separate poisons and governed by distinct laws, had not been established." It were easy to add to these remarks, only that I am at present concerned with fever as affecting British troops in India, and with reference thereto I consider that on the data already given in part in this communication, and more in detail in my special Reports on the subject, the following statement at page 69 of the second of those documents is borne out, namely: "I am fully justified in saying that by the evidence of authors and observers quoted, pathological conditions, now stated by some writers to be characteristic of, and confined to, a specific disease the result of a specific cause, namely, filth, exist also in fatal cases of various forms of disease, the result of non-specific causes endemic in tropical and sub-tropical countries, and that therefore, in the latter instances to apply a *specific* term to the disease merely from the existence of a particular *condition* is inappropriate and misleading."

h. It has been said that I have made use of the term *causation* in a manner "most misleading and unscientific, points being referred to as causes, which in reality are nothing more than conditions associated with the prevalence of disease." It seems to me, on the contrary, that with regard to the disease now under consideration one great misfortune is that the tendency of the day is too much to ignore the operation of surrounding conditions which are obvious, and to fix the attention too much

upon one *cause* or set of *causes*, assuming their existence when they cannot actually be discovered. In paragraph 4 of my paper, under the head of *Causation*, the following occur, and are discussed, namely: emanations from sewers, the use of impure water, fæcal contamination of air, violent and continuous exercises, exposure, conditions of the body itself, conditions of the surrounding atmosphere, &c. For my own part I have applied these expressions precisely as I have found them in the writings of authorities and writers whose works I have consulted; nor can I perceive the train of thought by which the expressions just quoted have come to be, I should say, *mis*-applied to them. With reference to this point of causation, quoting from page 16 of my first Report, I expressed myself thus in paragraph 4 of my paper under comment, namely: "Is it not the case that even here in England all professional men are not agreed as to the real cause of enteric fever; also that causation is so little understood that it gives us no help in diagnosis? But with regard to a form of fever, the definitions of which vary among themselves, and the causation of which is still undecided so long as we depart from generalities and individual conditions, inquirers in India, whose inquiries have failed to demonstrate certain specific causes of what has been indicated to them as a specific disease, have had very severe expressions applied to them. Meantime, however, their views are leavening opinion at home." That this remark is justified is, I submit, shown by the quotation from a recognised authority on enteric fever in England which occurs under section *a* of the same paragraph, namely, "I do not believe that there is any necessary connection between filth and enteric; and, indeed, I doubt if there be any at all. At the same time I would not like to say that any kind of filth might not contain enteric poison. The filth theory is really due to a name; and after a very anxious consideration of the evidence in favour of it, I have come to the conclusion that there is really none worthy of the name. The same may, I think, be said of drains, milk, and water supply. Some of the most recent of these are ingenious, and to *devout* believers no doubt satisfactory; but I am heterodox enough to doubt the whole thing. I think you maintain a climatic origin, that is, Trousseau's view, age, climate and overcrowding; and I don't think that we have got beyond that yet." Such are the *conditions* of *causation* to which my reference has been described as most misleading and unscientific. Such the authorities whom I follow.

i. "The study of climatology in connection with disease was of the utmost importance, but the assertion that an *infectious* fever was of climatic origin, when even the local circumstances under which it existed were not recorded, was damaging to the cause of epidemiology." Surely the paragraph thus quoted contains a number of misapprehensions. That under particular circumstances malarial fevers may diffuse themselves in the form of an epidemic, rendering it a point of difficulty to decide whether they are or are not infectious, has found various illustrations in India. Thus, at page 18 of my first Special Report, I write, "The Sanitary Commissioner with the Government of India, at pages 88, 89, and 224 of his Report for 1869, gives a number of particulars illustrative of the well-known fact in India, that epidemics as well as endemics of malarial fever suddenly occur from time to time at particular places." At page 76 of my second report the following paragraph on the same subject occurs, namely:—

"In 1843 Dr. Impy, of the Bombay service, writing of the 3d troop, horse brigade, then stationed at Chandmarie, near Mhow, expressed himself to this effect:—'It is well known, and brought home to us yearly, that troops become afflicted occasionally by temporary visitations (of fever), which are often as inveterate in type as universal in attack, and that the same stations, occupied by the same troops, remain for years after healthy, and as free from sickness as could be expected from the most salubrious locality; while on the other hand, presently, from some peculiarity or combination which has escaped us or is unknown, a type and vehemence are given to fevers which obscure their characters and almost set at defiance our resources.' Unless, therefore, a disease may prevail as an epidemic, and yet be incapable of propagation by infection, it is clear, on the authorities quoted, that a fever of this nature may and does originate from climatic conditions."

The following extract from the *Times* of July 19, 1880, is of importance in reference to the present subject. It is as follows:—"An official paper published in the *North-Western Provinces Gazette*, gives some details as to the epidemic of fever which prevailed in those provinces last year. The epidemic appears to have caused the death-rate to exceed the average by over 21 per 1,000, and it is estimated that 75 per cent. of the whole population suffered from the disease. The worst two districts were Bolundshahur and Alighur, in both of which the ratio of deaths from the fever was 113 per 1,000. Meerut came next with 81, and most of the other districts showed very high rates. Dr. Planck, the sanitary commissioner, describes the epidemic as essentially *climatic*, and ascribes the severity and great mortality to the vast number of persons who had been brought to a low state of health by the high prices and distress of the two previous years. The *specific* cause was, he thinks, *malaria*, resulting from copious rainfall of the year." I have italicised the words *climatic* and *malaria*. They precisely illustrate the sense in which they were used by me in the remarks to which exception has been taken. They also present an illustration at hand of the particular significance given to each by a medical officer of considerable Indian experience.

But with regard to the cases recorded in my special Reports two points are, I think, made perfectly clear by the information given from treating medical officers, namely, that in not one instance were the attacks of fever recorded in these documents traced to *infection*—in not one to *local*, that is, pythogenic conditions. On the first of these points I refer to column 11, Appendix A, pages 108 to 155, of my first Report, and 218 to 227 of my second. In these a few such remarks occur as "may have been," "supposed may have," "supposed," and so on, but nothing more definite occurs under this head, notwithstanding the obvious desire, as evidenced in the Reports quoted, to seek for specific rather than non-specific causes. With regard to the second point, namely, local conditions, I refer to the Sanitary Reports by individual medical officers, at pages 73 to 103 of my first Report, and to the *general result* of their information on the latter page, namely, that "in no instance has it been possible to find the existence of local and specific conditions of a nature to originate or influence the recurrence of specific pythogenic, typhoid, or enteric fever among British soldiers or their families within the Madras command." So far as local circumstances affecting the general sanitary condition of the troops are concerned, a reference to the "Form" of Reports furnished to me, given at page 73 of my first Report, will show that *all* such were most carefully considered, taken into account, and duly recorded in that Report. By all means let every possible improvement be made in these "forms," and thus aid further inquiry. Let my critics suggest some.

j. "Although it was obvious that climate governs every condition of life, health, disease, and death, yet that did not constitute it a cause of any special disease." Here, the circumstance being granted that "climate governs every condition" "of disease," I am unable clearly to demarcate in my own mind the exact point where it ceases to "govern," and yet not to "constitute a cause" of disease. In my paper now under remark, at paragraph 11 I quote from the more complete details at page 70 of my first and 77 of my second Report, where also the names of my authorities are stated, namely, "Inasmuch as the *fauna* and *flora* of localities are affected and modified by climatical influences—as the constitution of man is similarly affected—so, it is admitted by medical officers and others *who travel extensively*, that the pheno-

mena of disease are thus modified." "Each country has its own particular type of fever, depending more or less upon physical causes." "Infraction of Peyer's glands is endemic in some countries," and so on. Hence I consider that the remarks contained in that paper had the support of men whose travels authorised them to write as they did.

k. "Dr. Gordon's materials were also misleading, and having been obtained as the result of the issue of circulars to a large body of medical officers spread over a vast area they were almost necessarily untrustworthy." In the absence of particulars as to the grounds upon which these opinions are formed, I am unable to look upon them otherwise than in the light of abstract expressions. The circulars issued by me, from time to time, were so in furtherance of official instructions; they are reproduced at pages 204 to 208; they contain simply the items in regard to which information was officially sought from me; nor is it shown even now in what precise respect they were defective, or in what other way information from "a large body of medical officers spread over a vast area" could be obtained. I now mention the circumstance, however, that during my own time of service in the Madras Presidency, with one exception, I personally visited every station referred to in my Reports; thus the description of localities and their conditions therein given have the support of my personal observation. If any improvement can be suggested in the manner of collecting information regarding fever in India than the means I adopted, I trust it will be done, and is advantages demonstrated in the essays of competitors for the prize of 500 rupees handed over by me to the Government of Madras for this purpose. See Army Medical Blue Book for 1878, page 331.

l. "Even accepting the facts recorded in the returns issued, they in some important respects led to conclusions diametrically opposed to those embodied in Dr. Gordon's paper." That the interpretation of the *facts* alluded to, like that of many others, depends upon the light by which they are viewed, and also by the *quality* of observation recognised as "personal equation" is no more than natural, but the facts themselves remain. As between my own interpretation of the facts alluded to, and that by critic, there is, on the one hand, an Indian point of view, the result of *previous training*, according to results of continuous experience in that country; on the other interpretation of facts in India in accordance with training and theories of very recent origin in England — those theories themselves abandoned by not at all an inconsiderable number of capable observers, as already shown in this paper, and section *a*, paragraph 4, of that read before the Epidemiological Society.

Clinical Records.

NOTES ON A RARE CASE OF OTITIS EXTERNA PARASITICA.

By ROBERT TORRANCE,
Surgeon to the Throat and Ear Infirmary, Newcastle-upon-Tyne.

THE following case is communicated, with the view of enabling us the more clearly to understand and more successfully treat certain cases of otitis externa, not many years indeed having passed, since the profession became generally aware of the fact at all, that vegetable fungi were germinated in the auditory canal, and that they caused or aggravated inflammations of this part, and of the surface of the membrana tympani. The fungus here was discovered to be a species of aspergillus, which by the way, as already known (in one of its varieties), is the parasite most commonly found in the ear, and occurred in a young man, having what might be called a scrofulous otorrhœa. This was not the primary disease, but a consequence of a diffuse otitis, which had been of such a mild character for several years as scarcely to have attracted his attention, especially as he had been told that the disease would "wear away," and that medical assistance was of no avail for it. The formation of the vegetable mould, in his ear, had evidently been preceded, by what I believed to be an eczema, at all events some kind of an inflammation had first occurred which had loosened the epidermis, and when seen by me he was suffering from a sensation of fulness in the ear, with tinnitus aurium, vertigo, impairment of hearing, and pain, not severe as in acute catarrh of the middle ear, but a dull heavy sensation in the part. The objective symptoms consisted in the adherence to the walls of the canal and to the outer surface of the membrana tympani, blackish flakes nearly blocking up the whole of the passage, and which were mistaken by me at first for hard wax. The syringe, however, would not remove them, but the angular forceps used under a good illumination, by means of the otoscope detached them, leaving the tissue beneath reddened and tender, and when the microscope was resorted to as an auxilliary, it made the diagnosis certain to to be that of *Aspergillus Nigricans*, consisting of its three essential parts:—

1st. The mycelium, a dense network, or pseudo-membrane of delicate fibres, which formed the ground-work or roots as it were, from which the

2nd part, or fructifying portion (fertile hyphen), arose perpendicularly; and

3rd. The free spores which lay thickly strewn upon, and in the mycelium.

A portion of the specimen alluded to was planted upon lemon peel, placed in a close vessel, at a constant temperature of 80° F., when it gave at the end of the third day not, I must admit, a well developed growth of any form of aspergillus, but most distinct bastard specimens of it.

The treatment was exceedingly simple, but very tedious. The loosened epidermis and flakes of mould, were carefully removed every day by means of the forceps and syringe, and the canal was frequently douched with warm water, by means of Clark's douche. The canal was pencilled with nitrate of silver in strong solution after the cleansing process was over, not for the purpose of destroying the fungus, but to subdue the inflammation of the integument. Several agents were used as parasiticides, but were not found to be very efficacious, as the next day the growth was found to be reproduced. The most specific amongst them was the hydrochlorate of lime, which was used in the strength of two grains to the ounce of water. As is too often the case all the aural symptoms were not relieved, however, when the vegetable fungus had ceased to appear. Certainly, the most troublesome symptoms were so, by the destruction of the parasite, but the inflammation continued, long after the microscope had failed to find any traces of the mould in the auditory canal. Still, twenty-eight days after he came under treatment, he left me, with hearing distance for watch R. $\frac{9}{48}$, L. $\frac{14}{48}$. At eighteen feet distance he could hear and carry on a conversation in the ordinary tone, with his face away from the speaker, and some weeks after he was said to be still improved.

Note.—There is scarcely a doubt that many cases of vegetable fungous growths in the ear are often mistaken by us for impacted cerumen, and otitis externa diffusa. Since my attention has been called to the subject I can recall several cases of very obstinate inflammation of the auditory canal, which I now believe were cases of the growth of vegetable parasites in the part, none of which recovered from the affection, undoubtedly from not having used the specific parasiticides.

Translations.

DEAFNESS:
ITS DEGREES, CAUSES, AND THE VARIOUS MEANS RECENTLY DEVISED FOR DIMINISHING ITS INCONVENIENCES. (a)

By Dr. LADREIT DE LACHARRIERE.

Translated by W. DOUGLAS HEMMING, F.R.C.S.Ed., Bournemouth.

(*Continued from page* 113).

Von Troltsch adds: These histories are decidedly curious, and many ask whether these phenomena are not produced in cases where there exists a slight interruption in the chain of ossicles; for example, a separation of the stapes from the incus. We have often witnessed similar cases. We have often ascertained that deaf people who only distinguished words which were spoken into their ear, heard almost normally when they were in a carriage or a paved roadway, or in a vibrating medium, but experienced no change when they were simply in the midst of a noise. We think with the learned Wurzburg professor that the explanation of this phenomenon must be sought in the chain of ossicles; but instead of a separation, we think that it is in a consolidation of the articulations that we must look for the cause. We have always observed this phenomenon in persons affected with anchylosis of the ossicular chain, and we look upon the sign as sufficiently constant for us to recognise by it this condition of the chain. In anchylosis of the chain the sound-waves are no longer transmitted in conditions favourable for hearing, and it is only when the patient is in a vibrating medium that the chain partakes of the general agitation of all objects and is brought into a condition of suppleness more suitable for the transmission of sounds. Whatever may be the explanation of the phenomena, we have too often observed their coexistence with anchylosis of the ossicles not to affirm a relation between the two.

When deafness is not absolute there are other conditions in which its degree is variable. A large number of patients affirm that hearing is worse with them according to certain atmospheric conditions. These conditions are variable, and it is impossible to classify them with certainty. Some object to dry and cold winds, others fear a humid atmosphere, some complain of stormy weather, others find themselves better in rainy warm weather. We have endeavoured to interpret these differences. It has appeared to us that deafness, due to catarrhal affections, is worse in damp; that cases accompanied by congestive troubles, as those connected with herpes, or in which affection of the vaso-motor system was observed, varied in intensity according to the magnetic conditions of the atmosphere.

There are some appreciations of general causes difficult of determination and which it must suffice to indicate. In women it is a matter of almost constant observation that during the menstrual period the hearing is confused. I would also just note those fugitive and transitory glimpses, as it were, during which deaf people perceive sounds which for a long time they have not heard, and then after a few moments lapse again into their habitual state of isolation. I am convinced that these are not illusions, but I cannot give to them an explanation which satisfies me.

Deafness may be congenital or acquired. We shall at present examine only the causes of acquired deafness which may have either a cerebral or an auricular origin.

Deafness of cerebral origin may be hereditary. It is not rare to observe in the pedigree of a family a series of deaf people, without being able to point out an occasional cause. In such cases the deafness is almost always produced at nearly the same age, and it is rational to believe that heredity is the cause. We do not say that hereditary deafness always has a cerebral origin. This is, on the contrary, the rarest exception, and yet when we find no apparent lesion of the middle ear, no subjective phenomenon which leads us to suppose an affection of the internal ear, we do not know in what region, and in what conditions the acoustic nerve is affected and paralysed. "The hearing," writes Itard, "is of all the senses that which feels most promptly the least morbid dispositions of the brain, and that whose relations with this organ, both physiological and pathological, are most active. There are few deaf people who have not observed the influence of grief and of mental trouble on their infirmity. We know the profound abstraction of this sense in meditation and great pre-occupation of mind; and we may remark that hearing, more than sight, taste, or smelling, is enfeebled by an attack of apoplexy."

I have often had occasion to observe deafness as a precursory phenomenon of certain cerebral affections, and particularly of tubercular meningitis. Bouchut, in his lectures on Cerebroscopy, has pointed out certain lesions of the retina which may warn us of an outbreak of cerebral trouble. I do not doubt that if the expansion of the acoustic nerves was sensitive to our means of investigation, it would be equally possible to ascertain lesions analogous to those of the retina.

In the course of 1877 I was consulted for a charming child, æt. 9, very intelligent, who in the lycée at Paris, where he was, had gained all the success desirable at his age. For some months he had become deaf, and the dysecia had made such progress that he could no longer follow the lectures of his professor. The middle ear was intact, but labyrinthine sounds evidenced deeper trouble. My efforts were fruitless, and cophosis became almost complete. I ceased all treatment, and warned the mother to carefully watch the child's state; some months later I heard that it died rapidly of tubercular meningitis.

My accomplished friend Dr. Luys showed me the brain of a woman who had died in La Salpêtrière, and who had been completely deaf for more than twenty years, in which the posterior convolutions were the seat of considerable atrophy. The disappearance of some parts of the convolution showed vacua as large as the end of the thumb. Under what influence could such a morbid process be produced? We know not. Had the deafness been the consequence of the lesions, or had the loss of the function caused a wasting of the organ almost amounting to its disappearance? Many such questions we cannot answer, but these cases establish the fact that certain modifications of the brain may have intimate relations with deafness without causing other functional troubles.

Mention has been made of deafness due to syphilis, and I have myself had occasion to observe many cases of it in which the morbid cause was not, situated in the ear, but in the intra-cranial organs.

Numbers of children become rapidly deaf without our being able to trace any other cause than the retrocession of an exanthem, and without our being able to discover in the middle ear any traces of inflammatory disease; we may then suppose that it is on the brain itself that the morbid principle has directly acted. It is not a year ago that we were compelled to adduce this cause of deafness to explain the cophosis of a number of deaf mutes. It would seem that such a morbid cause should be but transitory; it is nothing of the kind however, and even when one is called immediately it is rare that efforts at treatment are anything but fruitless.

A large number of deaf mutes owe their infirmity to serious fevers, amongst which typhoid is in the first rank, and to meningitis. In these patients the brain seems primarily attacked in a large number of cases, and we can find no trace of lesion in the ear.

Lastly, we should mention convulsions in young children as frequent causes of deafness. These convulsions are manifested either during dentition or under an influence which eludes our appreciation. They may be the expression of a morbid condition of the ear. They may also be due to a purely cerebral cause. Whatever may be the cause of the convulsions they may produce serious modifications in the brain which cause the loss of hearing. We have observed many examples; sometimes they have been caused by strong emotion. Thus we observed a little boy who was terrified by Prussian soldiers who perpetrated on him the poor joke of aiming at him. He was seized with convulsions and remained deaf. We believe that convulsions, symptomatic of an affection of the digestive passages, or of a disease the seat of which is distant from the brain, may have similar results.

Hysteria.—We cannot close the list of diseases or nervous troubles which may cause deafness without mentioning hysteria. The ear pays its tribute to the fantastic mani-

(a) "Annales des Maladies de l'Oreille, du Larynx," &c. 1880.

festations of this neurosis. A characteristic of hysterical deafness is, that it is sudden in its appearance. Sometimes the deafness accompanies other nervous manifestations, at other times it is the only symptom of disease; the ears preserve an appearance of perfect integrity, patients complain of nothing except that they cannot hear. Another characteristic of hysterical deafness is, that it is complete; there are never any half-deaf people, patients hear absolutely nothing. I was consulted ten years ago by a high functionary of that period, whose daughter had become absolutely deaf without any cause appreciable by the family. I thought there was paralysis of the acoustic nerve of hysterical origin, and I recommended hydrotherapy in a special establishment. Some weeks later the father of this young girl came to thank me and to inform me of her perfect cure.

We must not confound hysterical deafness with deafness in hysterical patients. In the latter cases the deafness may be due to very different causes, and to all those which may cause it in other conditions, but it owes to the nervous malady variations sometimes unexpected. It is to this variety that we must attribute those fantastic and inexplicable modifications observed by Prof. Charcot at La Salpêtrière in his experiments on metallotherapy.

Local Causes.—These may be situated in the external meatus, the Eustachian tube, the membrana tympani, the tympanum and the organs contained in it, or lastly, in the labyrinth and its bony case. We will study these successively.

It seems a commonplace to write that obstruction of the external meatus may cause a marked degree of deafness, and that the ease with which this condition should be recognised should prevent such occurrences. It is not, however, always easy for an uneducated eye to recognise an obstruction of the deeper parts of the auditory apparatus, and it has several times happened to me to restore hearing to persons belonging to the well-to-do class of which they had been deprived for years. Among these cases two deserve mention.

I was consulted some years ago by the widow of a celebrated surgeon who had for many years been quite deaf of one ear. The external meatus showed, at its deepest part, an epidermic plug which had been scratched by the ear-pick, and which had a smooth greyish surface which had passed all the time as a fibrous, thickened, membrana tympani, showing no traces of the chain of ossicles. On comparing the two ears, it was easy to see that the depth of the two meati was not the same, and that the sound ear contained a foreign body covering the membrane.

Another case is that of a lady, æt. more than 80, whose deafness had long been attributed to old age. In this, as in the preceding case, re-establishment of hearing was complete, to the great surprise of both, who had little hope of cure.

The auditory meatus may be narrowed or its course obliterated by an osseous tumour. It would seem that this deformity is a congenital condition in some of the Indian races of America, among whom still the custom of producing artificial elongation of the cranium still obtains. We find in the Memoir of M. Delstanche, jun., (*a*) interesting historical researches on fifty-four cases of Titicacas thus deformed. Prof. Seligmann, of Vienna, has met with the anomaly in question five times; but it is important to add that he has not met with examples in another American tribe—the Avares, although their crania were deformed in an identical manner. We cannot, therefore, attribute the enormous proportion of exostoses of the ear observed among the Titicacas to the manipulations to which they submit their heads; it looks more like a predisposition of race. Welcker ("Arch. f. Ohren.," p. 163) met with these osseous excrescences in the Indians of North America with non-deformed crania, as well as in the natives of the Marquesas Islands. None of the crania of Caucasian races examined by this author presented this affection, although their number in the collections far exceeded that of the crania of foreign origin.

We have studied these morbid productions in all the cases cited by the authors, and in those which we have had occasion to observe, the deafness was more or less complete according to the degree of obliteration of the meatus. Seligmann and Welcker, having examined only the crania of the Indian tribes of America, could not say whether deafness was frequent among them. Deafness may also be caused by a cellulo-fibrous change of the auditory meatus. We frequently observe congenital imperforation of the auditory meatus, but this deformity may also be devoloped as a sequel of inflammations in the meatus. I have published a very interesting example occurring as the result of an otorrhœa, and by the rapid production on the diseased surface of a cicatricial tissue.

Polypi of the meatus are much rarer than those of the tympanum. They have, as a rule, their point of origin in the periosteum of the meatus, and present themselves as vegetations which may obliterate the meatus and cause considerable deafness.

Inflammations of the meatus, whatever may be their cause, by producing swelling of the soft parts, give rise to a certain degree of deafness; the acute symptoms which accompany them, the pain and the presence of discharge, make them easy to recognise. But there are some other affections of the meatus which, being developed slowly, cause no acute symptoms, and little by little produce loss of auditory sensibility.

Skin affections are common in the meatus. Some are accompanied on their appearance by moist secretion, which soon disappears, to leave the skin hardened, thickened, red, and covered with half-detached follicles; others are dry from the commencement like pityriasis. This affection is rarely primarily developed in the meatus; more often it has existed for some time on the scalp, and is propagated thence to the ear; it is at about the age of 40 when the hairs in the meatus become thicker and stronger that we see pityriasis appear. The scales from the head are caught and retained by the hairs, and a sort of morbid germination is soon produced. The pityriasis may be propagated to the external surface of the membrane, which is thickened, and causes aural trouble and deafness. Other parasitic affections have been observed in the meatus. These morbid germs belong to the genus aspergillus. It is to Wreden ("Arch. f. Ohr.," vol. iii.) that we owe the determination of their exact nature. Levi and Burnett, of Philadelphia, have also published interesting observations of them. The deposits found by them in the meatus always cause considerable deafness. In Levi's case the ear was the seat of abundant catarrhal secretion, but we may say that at first the dominant and only symptom of this condition is deafness. I need not mention insects, which always cause severe trouble, because the deafness in these conditions is not entirely secondary.

The Mineral Waters of Europe.

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS, FOR THE GUIDANCE OF THE PROFESSION AND THE PUBLIC.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,
President of the Pharmaceutical Society of Ireland, &c.

WITH NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,
Lecturer on Materia Medica and Therapeutics at the London Hospital.

(*Continued from page* 115.)

Therapeutics of the Foregoing Classes.

It is considered desirable to append a few remarks on the remedial uses of mineral waters in classes before proceeding to treat of individual springs. In so doing we shall follow the order adopted in the chemical division of this report. Inasmuch, however, as the imbibition of more or less liquid exercises no slight influence on the body, we are met by the preliminary consideration of the internal use of pure water. An adult will in health take an average quantity of nearly four pints of fluid a day; some thirsty souls take much more and some do with less. A few make simple water their chief fluid; others consume much milk; a larger number take a considerable propor-

tion of tea, coffee, cocoa, or other simple beverage ; too many almost exclude the simpler fluids by the amount of alcoholic liquors in which they indulge. In this last case, of course, the effect of the alcohol masks that of the fluid, but we must not forget that the amount of liquid drunk and the time at which it is taken exercise some influence. Of course, the amount of liquid received has to be counterbalanced by that removed, so that the skin, lungs, and kidneys are called upon to get rid of the average four or five pounds of water a day, and of any excess that may be injested. As the water is taken into the system and is the vehicle for the removal of waste it may be regarded as in some sense washing the tissues. It is commonly said that very little water passes directly through the pylorus into the intestines, but Küss is of a different opinion, and the writer endorses his view—more especially when large quantities are taken.

But the water thus required to maintain the balance of the system is only a small part of that which is always at work in the economy. The quantity daily poured with the secretions into the alimentary canal, and again re-absorbed by the lymphatics and termini of the vena portæ, is variously estimated at 12 to 24 pounds. This water is the purveyor of various solids which are precipitated and left behind, and the solutions in question must contribute their share to the manufacture of the chyle. Water freely passes from the stomach into the vena portæ ; thence it goes through the liver, where it becomes charged with the products of that organ, and brings them again into the intestines where they are precipitated. Hence we may understand the repute of free water-drinking as a cholagogue, and as powerfully assisting the abdominal circulation. Apart then from its mechanical effect in the primæ viæ, which varies with the quantity imbibed at a time, water may be regarded as the great diluent, solvent, and eliminant. It dilutes the contents of the stomach and intestines, and thus acts as an aperient. It also dilutes the whole mass of the circulating fluids ; but probably the blood is only influenced thus for a brief period, its specific gravity being maintained with tolerable uniformity. We have seen how it dilutes the bile and thus acts as a cholagogue. In the same way it is a diuretic and diaphoretic by dilution of the excretions of the kidney and skin, and the same may be said of its effect on all secretions. Add to its diluent its solvent powers, and we see why it is the most valuable eliminant : dissolving various substances and increasing all the secretions by which they are removed, it increases tissue changes, and thus loss of body would ensue unless counteracted by the fresh arrival of aliment. It may thus increase appetite, and prove the best tonic ; but if appetite fail, or food cannot be obtained, it would hasten wasting. By removing waste tissues it is believed that it may thus affect morbid deposits, though this power is more frequently attributed to medicinal waters.

The temperature at which water is drunk has a great influence. Absorption appears to take place at about the temperature of the blood, and to secure rapid removal from the stomach by absorption it should be taken at about that point, and in small quantities at a time. Cold water in small quantities stimulates the stomach and assists digestion. A full draught is apt to impede that function—in weakly people "lies heavy" for a long time, and the danger of drinking very large quantities when the body is hot and exhausted, is well known. A glass of cold water early in the morning is an excellent aperient, stimulating the peristaltic action by its temperature, and promoting the secretions in the way already described ; a draught rich in carbonic acid is still more effectual. Cold water may be given when even the temperature is high, and it does not give rise to discomfort. On the other hand warm water is more grateful in many painful affections of the abdominal organs ; it is better to increase the action of the skin, to promote other secretions, and possibly to stimulate the absorption of morbid deposits ; as a cholagogue it is often efficient if taken regularly at bed time, or night and morning. In laryngitis and bronchitis the use of hot drinks is well known as a popular remedy. Warm beverages are also popularly regarded as more refreshing than cold. Excess in drin king liquids either warm or cold gives rise to certain complaints well-known to medical men, but as this report is intended to be restricted to the bottled waters, it seems unnecessary to describe the evils that are sometimes produced at certain springs.

We have next to consider the action of mineral waters. The effect of a glass of water containing a fixed amount of solid or gaseous substances might be supposed to be the same as a similar dose of the active ingredients. Usually more fluid is taken than in pharmaceutical preparations ; hence we have to do with the effect of the water as well as the medicine ; and with the variation induced in the latter by dilution. The former we have seen depends on the quantity drunk, the time at which it is taken, and its temperature. With regard to the latter, the effect of solids is perhaps better understood than that of gases. Some mineral waters are charged with large quantities of solids, for example, some of the stronger, bitter, saline, purging waters ; others contain an almost inappreciable quantity of mineral ingredients. These solids are absorbed with the water, and produce their usual medicinal effects, but it is to be remembered that dilution tends, as a rule, to increase that action. Thus a small dose of sulphate of magnesia or soda in a large quantity of water will prove as active a purgative as a large dose less diluted. Then, again, the frequency of repetition in many cases is an important question, for on this depends whether the ingredient be circulating in the system almost constantly, or only for a brief period. This depends in its turn on the rate of elimination and the frequency of the dose, a point which, in reference to mineral waters, has not been sufficiently attended to. The effect of the gases is less understood. Carbonic acid is an agreeable stimulant to the stomach, from which, however, most of it is speedily eructated, but some of it passes into the intestines and stimulates

peristalsis. So marked is this effect that carbonated waters are advantageously substituted for salines in many cases in which the latter are still frequently prescribed. Constipation from torpor of the bowels is not amenable to the more irritating laxatives of saline waters, but may often be overcome by more simple remedies, such as the popular glass of cold water, fasting; or the still more appropriate use of a highly carbonated, but not purgative, mineral water. Further, the carbonic acid gas has the power of holding other ingredients in solution, and making the dose more palatable. Of the effects of nitrogen, sometimes vaunted as an ingredient, nothing positive is known. Minute quantities of sulphuretted hydrogen are supposed to have a value as pronounced as the flavour of the water which contains this gas. Of other gases nothing need be said here.

(To be continued.)

THE MEDICAL ASSOCIATION MEETING AT CAMBRIDGE.

The four days' doings of the British Medical Association have come and gone since our last issue left the press, and on the whole the gathering may be recorded as an unequivocal success. Many circumstances in its favour were even anticipated, and the anticipation, we may say, has been realised. The proximity of Cambridge to the metropolis afforded great facility for the attendance of London men and the reading of London communications, and there was, therefore, an excellent list of papers to be read on the "orders of the day" of most of the sections. Moreover, it was possible for the busy men of the great city to run down after their morning's work and take part in the festivities of the evening at Cambridge, and many of them did so, while the powerful influences of University prestige and Collegiate hospitalities were of themselves sufficient to make the meeting attractive and successful. The colleges had, indeed, lent most potent aid to the accommodation and comfort of the visitors, for they placed their rooms at the disposition of very many of the visitors, and thereby added the charm of University residence to the other attractions of the city of Cambridge.

The afternoon of Tuesday saw a goodly number of the members of the Association and of the ladies who accompanied them congregated in the noble and beautiful chapel of King's College to inaugurate the meeting by a choral service and a sermon from the Lord Bishop of Ely. The address was eloquent and eminently appropriate to the occasion, but considering that many of those present had travelled all night and were longing for a stroll through the college meadows and courts as a change from the dusty heat of the railway carriage, it might, we think, have been abridged or divided without any sacrifice of the appreciation of the audience. The service, however, was a most imposing initiation of the Association's proceedings, and worthy of imitation whenever the beauties of cathedral architecture and music and episcopal eloquence are at hand.

The first general meeting of the Association was held on the same Tuesday evening at the Senate House, and in due course the first business was the relinquishment of the chair by Dr. O'Connor, of Cork, and its assumption by Dr. Humphry, the new President, and the host of the Association for the time being.

Dr. O'Connor expressed himself, as he always does, in a kindly spirit and with a venerable presence which ensured to him the sympathy of his audience. He briefly recapitulated the successes of last year at Cork, and added: Let us not look for great discoveries, for they do not come every year, nor always every century, but be satisfied to extend our knowledge. This, I may say, is the characteristic of the generation in which we live, not alone to advance knowledge, but to disseminate it, till it comes closer to those who are engaged in using it for the purposes of life. It is in this way that knowledge may be called power; and there is no institution that has aided so much in the dissemination of knowledge as that which has opened its venerable halls for our meeting. And never have they proved their utility better than by receiving and fostering within their walls the medical profession, whose interests we are met to advance to the utmost of our ability. In this University medicine becomes associated with classical literature, which has been the solace and comfort of a hard-working profession, and particularly at a period of life when a man's working day is past; and associated with it are the stricter sciences, that are so necessary to enable the physician to reason well about the problems that come before him, to distinguish truth from error, to distinguish assertion from proof.

Dr. Humphry ascended the throne of the Association amidst plaudits which proved not only that he was popular in his person, but that the Association felt he was the most deserving occupant of the chair; and he delivered an address which was brilliant and instructive (for those who could hear it), and which may be read in abstract in our columns by those who did not. The Senate House would seem to have been constructed with a careful regard to the killing of articulate sound, and even Dr. Humphry's exact articulation did not suffice to convey his words to those at a distance. By those who were so placed as to hear and enjoy, his address was pronounced admirable. The suggestion made by the President as to the united action of the members for the purpose of collecting facts in medicine, surgery, and pathology was at once accepted by the meeting, and a resolution of thanks to him adopted thereupon.

At the conclusion of the presidential address, and after a warm vote of thanks to Dr. O'Connor, Dr. Carpenter proceeded to read the annual report of the Council, but before he had uttered half a dozen words he was made to understand that the meeting was not disposed for the dullities of business and finance, and accordingly the report and statement of accounts were taken as read, and passed *nem. dis.*, not, however, before Dr. Stewart had given utterance to a most wise and solemn warning against such a method of doing business. The caution administered by him was reasonable and, in the interest of the Association, most needful, but it cannot, we think, be expected to produce any effect as long as the pure business debates and financial calculations are huddled up within the expiring minutes of an oratorical congress. Each balance sheet and report of the Association contains necessarily much matter for comment, even by those who see no reason for finding fault, and without doubt the Association will, as Dr. Stewart said, live to regret it, if it ceases to take an interest in the practical business details of the organisation. However gratifying it may be for the Council to have its work approved without being examined, it must be discouraging to them that their labours should pass without appreciation, and it is certainly dangerous for any large organisation such as this to give its stewards to understand that it asks for no account of their stewardship. We strongly urge that a special hour be given on the second day of each annual meeting to the report and accounts.

The final proceedings of the first day at Cambridge was the adoption of a motion by Dr. Norman Kerr to the effect that in future the dinner ticket should not include the cost of wine in its price. When Dr. Kerr rose to move this proposition, his reception was the reverse of encouraging, but having spoken with much force and with praiseworthy courage respecting the evident injustice of compelling temperance men to pay for the wine of non-abstainers, he received such support from all parts of the room, that the Committee of Council saw the wisdom of accepting it, and no doubt we shall next year have the presence of the teetotallers at the annual dinner.

Wednesday.—Second Day.

On Wednesday morning a large number of persons assembled in the Senate House to hear the address in medicine delivered by Dr. Bradbury. The address occupied an hour in its delivery, and at its conclusion a hearty vote of thanks was accorded him. We shall give a full abstract of it in our next.

An attempt was made to clear the Senate House in order to prepare for the special Congregation to confer the honorary degree of LL.D.; but this effort was only partially successful, so as to enable a preparation to be made for the usual ceremony. The undergraduates' gallery contained a sprinkling of ladies, as well as dons and strangers, besides the usual occupants of the space. At length the procession arrived,

headed by the Vice-Chancellor, all the doctors (actual and designate), wearing their scarlet hoods ; and marched up the Senate House. Some little time was occupied by the men whom the University delighted to honour going up to the table of the Registrary to sign their names in the University book. When Sir William Jenner was recognised, he was generally cheered ; but the groans which greeted the appearance of Sir William Gull were merely the foreshadowing of the storm which was later on to break forth, and which stopped the Public Orator for a time from going on with his oration. The reception of Sir William Gull was indeed the episode of the occasion, and was as complete a demonstration of disapproval of his recent conduct in the Guy's case as could be conceived. If anything can convince the learned baronet that he cannot cultivate notoriety by such means without sacrificing professional position, the hint which he received at Cambridge ought to do so. Although Sir William Gull's professional brethren did not take part in the demonstration to any considerable extent, the opinion was freely held and expressed that the display of feeling by the students was fully deserved.

The Public Orator, before presenting the candidates for honorary degrees, addressed some felicitous words of welcome to the members of the British Medical Association. He said :— "In ipso limine orationis nostræ nihil auspicatius esse arbitramur quam ut vos, qui consilorum vestrorum sedem hanc curiam elegistis, totius senatus nomine omnes salutemus. Qui salutem iliis totiens attulistis, vosmet ipsos omnes salvere jubemus. Athenienses quidem olim vestro illi Hippocrati auream coronam in theatro publice decreverunt ; nos autem, ut nostram erga vos omnes benevolentiam aliquatenus indicemus, e tot viris de humano genere bene meritis, nonnullos, velut exempli gratia, nostra corono qualicunque hodie ornare volumus, qui honus idcirco illis laudi est quod vestra omnium, uti speramus, consensu comprobatur." In presenting Dr. C. E. Brown-Séquard, F.R.S., Professor at the Collège de France, Paris, the Orator made a feeling allusion to the death of Dr. Paul Broca, the eminent surgeon and anthropologist, to whom an honorary degree had been granted, "atqui laurea illa in cupressum mutata est." With regard to Dr. Séquard, he was commended as worthy of honour on account of his investigation of the functions of the nerve centres. Dr. Chauveau, of Lyons, being unavoidably absent, Dr. F. C. Donders, Professor of Physiology at Utrecht, was next presented. Reference was made to the fact of his being an Honorary Fellow of the Cambridge Philosophical Society, and a warm eulogy was pronounced on the success which he had achieved by combining the study of mathematical optics with the physiological investigation of the human eye. Dr. Gross, of Philadelphia, was described as the Nestor of scientific surgery. Sir William Jenner was introduced as celebrated for his great knowledge and success in the treatment of fever, "quæ pulsat pede æquo pauperum tabernas regumque turres." In presenting Sir William Gull, the Orator spoke of him as a man well known in the medical world for his great practical ability in recognising and treating diseases and for his application of great physiological knowledge to the practice of medicine. In introducing Sir George Burrows, the Orator referred to his success as a mathematician at Cambridge, and to his connection with Caius College, of which he was formerly Fellow and tutor. Allusion was made also to the fact that he had filled the post of President of the Royal College of Physicians, and was one of the physicians to the Queen, "quam usque ad hunc diem omnes et vivere et valere gaudemus." The Rev. S. Haughton, M.D., F.R.S., Fellow of Trinity College, Dublin, was alluded to as a successful worker in theology, geology, zoology, geography, physics, mathematics, and medicine. Of him, in the words of Celsus, it might be said, "Naturæ rerum contemplatio, quamvis non faciat medicum, aptiorem tamen medicinæ reddit." Mr. William Bowman, F.R.S., was praised for his exertions in early life in unravelling the minute anatomy of the body, leaving others to build on the solid foundations made by himself. Reference was also made to his success as an oculist. Mr. Joseph Lister, F.R.S., was referred to as an eminent physiologist and surgeon, best known for his investigation of the germ theory. The revolution he had introduced into the treatment of wounds was also alluded to, and the Orator concluded as follows :—"Itaque cum tanto viro nos quoque libenter fædue icimus, dextraæque illi intrepidæ dextram hospitio jungimus." Dr. Denis O'Connor, the ex-President of the British Medical Association, was congratulated on the way he had discharged the duties of his office, and a fit allusion made to his successor, Prof. Humphry. In presenting Mr. John Simon, C.B., F.R.S., the Orator described him, not only as a man of great literary ability, but also as a great authority on matters of sanitary science, which had been used to the great advantage of this country. Lastly, in presenting Mr. Andrew Wood, M.D., he alluded to his translation of Horace and to his ability as a medical man.

The Vice-Chancellor afterwards entertained the newly-created doctors and a distinguished company at luncheon at Corpus Christi College.

At two o'clock the sectional work of the meeting began and for the purposes of our present Report we are obliged to epitomise the scientific work of the section in this and the following days by saying that there was ample material of interest and value. The addresses of Dr. Paget in the surgical section, and that of Dr. Crichton-Browne in the psychological department were specially noticeable, while great interest was evoked by the debate on Antisepticism, in which the assault was led by Professors Erichsen and Savory, and the defence conducted by Professor Lister himself. On the last day of the meeting it became evident that it would be quite impossible to dispose of all the papers on the sectional lists, and many of them had to be taken as read.

In the evening the president of the Association and the reception committee gave a soirée in the Fitzwilliam Museum and the grounds of St. Peter's College, and it was most successful. The soirée was attended by between two and three thousand persons. The interior and exterior of the fine building was lighted with Dr. Siemen's electric light, and with the most perfect success. The pretty grounds of St. Peter's College were lighted up with hundreds of transparencies, making a scene of fairy-like beauty. The evening was beautifully fine and warm, and vast numbers of the guests were glad to escape from the crowded rooms of the museum and promenade the gardens, listening to the band and the singing of the Orpheus glee singers. The whole of the arrangements were carried out perfectly.

Thursday.—Third Day.

On Thursday morning the National Temperance League breakfast, at the Lion Hotel, was very numerously attended. In fact, so large was the attendance that the great assembly room failed to accommodate them, and a portion of the company had to take breakfast in the coffee-room. Mr. Samuel Bowley presided, and was supported on his right by Dr. Denis O'Connor, the late president of the British Medical Association, and on his left by Mr. Wm. Fowler, M.P.

The third general meeting of members was held in the Senate House, under the Presidency of Professor Humphry. Twenty members of the Council were appointed to act as the Committee of Council for 1880-81, to which Committee was referred the question of the place where the annual meeting of 1881 should be held, and who should be the president elect. It was reported that Worcester intended to invite the Association to meet in that city in 1882 for its jubilee meeting. After other matters of an administrative character had been dealt with, Mr. Timothy Holmes, M.A., F.R.C.S., Surgeon to St. George's Hospital, London, delivered the Address in Surgery, which we hope to publish in abstract next week, at the conclusion of which the gold medal of the Association for distinguished merit, which had been awarded by the Committee of Council, was presented to Dr. Acland for Dr. Wm. Farr, M.D., F.R.S., D.C.L., C.B., the latter being unavoidably absent through illness.

On the same evening the Annual Dinner took place in the hall of Trinity College, the number of diners being limited to 350. Professor Humphry, of course, presided, having on his right and left the Right Rev. the Lord Bishop of the Diocese, the Vice-Chancellor of the University, the Mayor of Cambridge, Sir James Paget, Dr. Brown-Séquard, of Paris ; Dr. Gross, of Philadelphia, U.S.A ; Dr. Michael Foster, Professor Acland, Oxford ; Mr. Husband, York ; Rev. Dr. Haughton, Dublin ; the Public Orator, Professor Latham, Professor Ball, Paris ; Professor Liveing, Professor Longmore, Netley ; Mr. G. F. Cobb, vice-master of the college ; Rev. G. F. Browne, &c.

After the usual loyal toasts,

The President gave "Army, Navy, and Reserve Forces," and alluded to the services of the medical officers of the forces and the part they contributed to the efficiency of our forces.

Professor Longmore responded, and bore testimony to the bravery with which so many of his professional brethren stood fire as non-combatants, when war rendered their presence neeessary on the battle-field, and the way in which

they performed the equally onerous duty that devolved upon them in the hospital.

Professor PAGET proposed "The Bishop and Clergy," and returned thanks to the Bishop for his excellent discourse in the King's College Chapel.

The BISHOP, in responding to the toast, spoke of the medical and clerical professions as being two orders of a similar character, the work of both being bound up together. He rejoiced to think that there was no jealousy between the members of his profession and theirs. He had always found the greatest help from the medical profession in the work of a parish priest, and he remarked that it was most important that the union should be cemented and continued, and he hoped it would be by the gathering of that week.

Dr. ACLAND proposed "Success and Prosperity to the University of Cambridge." It was a difficult task that he was asked to do, to propose this on behalf of a body of men gathered together from all parts of Europe and America. He also adverted to the past and present of Cambridge, which he described in glowing colours. He indeed must have a heart of stone that could enter Trinity College without emotion.

The VICE-CHANCELLOR responded, accepting the way in which the toast had been proposed as an expression of kindly feeling from such a body as that. He thought that all must have been fascinated by the great past history of the University. He admitted that Cambridge had done but little for medicine in the University in the past. He was not prepared to admit that there had been such partiality for the mathematical and classical tripos as some contended. He was sure that the University would do all that was possible to promote a broad and liberal education. He proceeded to propose "The British Medical Association," and coupled with it the name of Dr. Carpenter. It had afforded them great pleasure to have had the opportunity of welcoming this Society at Cambridge.

Dr. CARPENTER, as president of the Council, responded for the toast, and alluded with great satisfaction to the way in which all the members of the Council devoted themselves to such work as was necessary for the transaction of its business.

Mr. HUSBAND, of York, the Treasurer of the Association, proposed "The Health of the Mayor of Cambridge."

The MAYOR (H. Rance, Esq.) responded.

Sir JAMES PAGET proposed "The Health of the President." His knowledge of the President was not merely of yesterday, as upwards of 40 years ago, their President of to-day did him the honour of asking to be allowed to be his pupil, and from that time to this a friendship of the most intimate kind had existed between them. He had by constant observation been a witness of the wisdom and benevolence of his character, and as the possessor of those qualities, which not only made a true-hearted friend, but enabled him to do good work, which was year by year justly and cordially recognised. Dr. Humphry came down to Cambridge as a truly practical man, and he had continued to retain his connection with practical work, but had (which very seldom happened) besides being practical, become even more truly the scientific man. When Mr. Clark ceased to be professor of anatomy, in 1866, it was feared that his loss would be so great that his successor could not be found, but Humphry succeeded to the chair, and Clark had hardly been missed. He, in conclusion, asked them to drink the President's health with three times three.

This invitation was responded to in the most enthusiastic fashion.

The PRESIDENT responded. He came to Cambridge, but it was Sir James Paget who sent him, and he only acted under his orders. He it was who had planted him (Dr. Humphry) on this fair spot, which he had loved so well, to do the work he so much loved. He conceived it to be a very great honour to be the captain of that noble band. Their thanks were due to the University for the kind way in which they had contributed to the success of the present visit of the Association to Cambridge, by placing at their disposal all the University buildings, to the colleges for the hospitality they had shown, to the Mayor and Corporation of the town for also lending the Guildhall and other public buildings. He apprehended that the recollection of this visit would live in the memory of many members of the Association for years to come. (Applause.) He then proceeded to propose the toast of "Our Guests."

Dr. BROWN SEQUARD responded.

Dr. GROSS remarked that this was the third meeting of the British Medical Association which he had had the honour of attending. The first was when it met at Oxford in 1868, the second was when it met at Birmingham in 1872, and now the present meeting at Cambridge. He was proud and happy to be present and to consider himself very much of a Briton. On their side of the Atlantic they spoke the same language that was spoken here, they were engaged in teaching the same branches of knowledge, and he was connected with the same noble profession. He felt that it was of the utmost value to the future peace and concord between the two countries that such kindness should be shown to each other. Whilst such kindly intercourse was perpetuated between the two countries, there never could be war between them. (Applause.) He was exceedingly grateful and proud of the honour which had been done him both at Oxford and at Cambridge, and for which he felt himself personally indebted to Dr. Acland, of Oxford, and their President, with the noble Vice-Chancellor. He could not regard these honours as intended for him personally, but to show their regard for the American people Government. (Applause.)

Madrigal: "Flora gave me fairest flowers."

Dr. A. P. STEWART proposed "The Readers of Addresses and Officers of Sections," for which

Dr. BRADBURY and Mr. SAVORY responded.

Rev. Dr. HAUGHTON (Dublin) proposed "The Editor of the *Journal*," and that gentleman responded.

The PRESIDENT proposed "Trinity College," and referred in appropriate terms to the kindness of the Master and Fellows in lending them that fine and interesting building for the holding of the dinner.

Dr. MICHAEL FOSTER responded.

Dr. WADE proposed "The Reception Committee and Secretaries," for which

Dr. ANNINGSON responded.

FRIDAY.—FOURTH DAY.

This morning, Dr. MICHAEL FOSTER delivered, in the Senate House, before a general meeting of the members, the Address on Physiology, which was received with great applause.

The concluding general meeting of the Association took place at the Senate House, at 1.30.

A discussion ensued on the Habitual Drunkards' Bill, and the report of the Committee was adopted, the Committee being re-appointed. On the motion of Professor Rogers, a resolution was carried that steps be taken to prevail upon the Government to introduce some legislation whereby habitual drunkards of the pauper class may be placed under restraint.

Various other matters were dealt with, and a considerable number of votes of thanks were passed, amongst which were the Vice-Chancellor and the University, for the use of the Senate House, Fitzwilliam Museum, and other buildings; the Bishop of Ely, for his sermon at King's, with a request that he would allow it to be published; the Mayor and Corporation of the borough, for the use of the Guildhall and Corn Exchange; the Master and Fellows of Trinity College, for the use of the hall for the dinner; the Master and Fellows of Peterhouse, for the use of the grounds; the Masters and Fellows of St. John's, and to the Masters and Fellows of the various Colleges for their hospitality; to the local secretaries and the reception committee, to the profession of the town, and the inhabitants generally, for their hospitality.

During the meeting there have been museums in the large assembly room, Guildhall, and the Pathological Museum. These have attracted considerable attention.

The garden party at King's on Friday afternoon, and the conversazione at St. John's in the evening, concluded the proceedings, with the exception of the excursions to Ely, Peterborough, Bedford, Royston, &c.

ANNUAL MUSEUM.

SURGICAL INSTRUMENTS, APPLIANCES, DRUGS, PREPARATIONS, FOODS, &c.

THE exhibit of new instruments and other medicinal requirements was this year of a very excellent character, the number of firms represented being in excess of former years.

We need not however wonder at this, when we consider the favourable locale of this meeting, and its close proximity to the metropolis. The exhibitors must have been pleased at the room this year assigned to them, it was the central focus for the members, so that there was every chance afforded of their goods being seen, examined, and, we hope, that a sufficient number of orders have been taken to pay the enterprising firms who have taken the trouble to open stands.

Such museums are educational, members in the provinces cannot see the newest appliances unless an opportunity is afforded them by exhibitions of this nature; both buyer and purchaser are benefited by this arrangement. The same is true of drugs.

In our notice we hardly know where to begin, so plunging at once *in medias res*, we, as the weather is so warm, turn to "Zoedone," the sparkling beverage which was so liberally distributed by the manager of the new company, Mr. Moss, to the heated and thirsty associates. So much has been said about this drink that we need not gild it any more; it is the drink of the present and the future. It is pleasant, light, nutritious, sparkling, non-intoxicating, though we heard some reports in the room that with the addition of a little Irish whisky, it approaches the nectar or ambrosia of the gods, the formula for which has been revived by Mr. Johnson. Zoedone is a success. From this to food is a step, so I pass on to M. Dougall's flour, which presented a white, pure appearance, and the bread made from it seemed of a very good character. We have no doubt that M. Dougall's process of treating flour will prove useful. Next M. Dougall's stand, the well-known firm of Burroughs and Co., 8 Snow Hill, London, had a collection of the preparations for which this firm is distinguished, and the number of physician's samples for distribution showed that Messrs. Burroughs were determined that the profession should test their wares. Their American specialties attracted much attention. As agents for Wyeth's, Philadelphia, they had the various preparations, compressed tablets of potash, ammonium, &c., the specialties of the American house. They had a supply of Fellow's Syrup, hypophos comp., a preparation well deserving of the notice of practitioners, and which promises to have a large sale. Our American cousins are thorough go-a-head people. English chemists will have to look to their laurels. We saw some samples from the house of McKenon and Robbins, New York, on Messrs. Burroughs' stand, showing to what perfection pill-making is getting. These pills included monobromate of camphor, sulphide of calcium, iodoform, biniodide of mercury, sulphate of morphia, and they almost would tempt one to indulge in a course of pills. Kepler's Malt Extract was plentiful. We have spoken of this before, and readers of the *Press and Circular* know our opinion as to its value.

In this avenue Newbery and Co. had a good show of their pearl-coated pills, and Warner's specialties; Bealle showed soda and other mineral waters; the Glass Bottle Company had samples, and Cooper, of 26 Oxford Street, London, had many specialties, amongst which we may particularly mention his effervescing lozenges, the cupric test pellets and the new injection tube. They only require to be known to sell, and when they are well advertised in the medical papers they will no doubt go off.

Vaseline was a strong specialty with Cheesborough. This basis for ointment is so well known that it is unnecessary to point out its advantages.

Prescott and Co., 8 South King Street, Dublin, were strong in slides, optical instruments, and considerable amusement was caused by a very ingenious toy, called the Electrophorus, and by the gyrations of the serpent doll when placed in it. We regret we did not see more Dublin houses represented.

Schachts and Co., 26 Finsbury Pavement, had a very good preserving fluid, with specimens on view. It seemed to answer its purpose well, as the preserved lung and other preparations proved.

Passing into the next division we came on the collection of Corbyn, Stacey, and Co., and we need hardly say they were strong in their specialties, with the addition of the new remedies which are now attracting the attention of speculative physicians. Their specimens of caffeine, duboisia, euonymin coloin, eserine, rava rava, propylamine, &c., were very good. We noticed that Corbyn had Valentine's Meat Juice on view, and for taste, we tried it. And the cold aqueous solution we can safely recommend as agreeable in taste, with a well-marked pleasant meat flavour, and we cannot but think it will prove a useful addition to the sick dietary. It is in a very convenient form for use. The Chian turpentine of Corbyn's was a very good specimen, so that there should not be any difficulty now in testing this drug.

Cancer cures and curers have been heard of before to-day. In the days I believe of the well-known surgeon, Colles, some preparations of iron were used, and Colles is reported to have said, "they may talk about iron in cancer, but the only preparation of steel that I know is of any good, is cold steel, in the shape of a knife."

From cancer to neuralgia. Allen and Hanbury, Plough Court, London, had a fluid extract called Tonga, for distribution. It is said to be a specific for neuralgia. We hope those who obtained samples will report progress. The other preparations of this well-known firm were of the class for which the house is noted. Their Chrisma has now obtained a standard place.

Young and Postan's pharmaceutical preparations are well-known. Their pepsine is very good, and in their glycerole of pepsine the practitioner will find a highly concentrated preparation. The granular effervescing specialties of this house were well worthy of inspection.

Brady and Martin, Newcastle, have a large assortment of drugs and sundries.

Savory and Moore's stand was distingished by the favourite exhibits of this firm. We noticed that the medicated lamels for internal use, the discs for hypodermic injections, for ophthalmic use, the blistering gelatine, the liquid extracts of the digestive ferments, by means of which the firm have gained such a well-deserved reputation amongst the profession. The drugs of this house are of a pure, high, clear character, and their preparations may always be relied on as pharmaceutically pure and accurate.

From the provinces came Harvey and Reynolds, with an excellent assortment. We may direct special attention to their liquid extract of ergot. It is not a pleasant looking fluid, but it has this great merit; it is certain in its action, and is one of the best preparations the accoucheur can have; he may rely on it. Their solution of belladonna for painting on the part is a very useful preparation. Southall Brothers and Barclay, Birmingham, had a good collection. We may draw particular attention to their new sanitary towel for child-bed, and ordinary use as a useful household necessity. Bowdler and Bickerdills showed their absolvent phenol, for which a prize medal was awarded at the Paris Exhibition, 1878; and their specimens of carbolic acid.

Mackey, Mackey, and Co., so well-known by their preparations of quinquinine, exhibited a pure and useful stock of well-known drugs, besides the latest novelties, such as homomyne nitrate of amyl, picrotoxin, &c.

Burgoyne, Burbidges, Cyrian, and Fannin, had a stand devoted to the productions of Parke, Dawe, and Co., of New York, and in their list were some of the latest novelties in American productions. The new alkalines were well shown, and, as we have previously said, American pharmaceutists prove incontestably that they are well able to hold their own with the old country. The taste for novelties is growing, and the supply promises to be equal to the demand. Whether to the advantage of the patient we know not.

One result of our inspection of the drugs is that we feel convinced that the pharmaceutical ingenuity of our English speaking races is receiving a great impetus, or being developed by the increasing demand for new medicines, and for a more palatable production of remedies.

It is important that medicine should be administered in a palatable form, though we cannot but think that some limit must be put to the production of new remedies, for life is too short, at the present rate of production, to become acquainted with them all, or even to test them.

The prescribing physician is more fortunately placed than the dispensing general practitioner in regard to new drugs, for he can order the newest thing in the market, as he throws the expense and onus on the chemist in obtaining it.

The general practitioner, besides requiring an enormous surgery for storage, would have to consider whether it would pay to keep all these new medicaments. This is an argument in favour of the abolition of private surgeries, and it seems to be a very forcible one, for the public, who are the real persons interested, thus lose the advantage of being supplied with the newest drugs. We believe there is a strong feeling in favour of the general abolition of dispensing, and we consider it would be better for the profession, and for the wholesale and retail chemist if this were done.

The surgical instrument makers were well represented. Coxeter and Sons had a stand filled with the latest appliances, though they seemed to make a specialty of constant current batteries. They claim for their batteries the merit of being the cheapest of their kind in the market, as no acids are employed, and the battery does not require re-charging, cleaning, or attention.

The elements of the battery, though of the "Leclanché" type, differ essentially from the forms hitherto constructed, and are absolutely free from polarization. The carbon is replaced by platinum, which has the highest electro motive force obtainable; this, combined with the manganese, gives greater strength of current, constancy, and durability, and allows of the cells being made very much lighter and smaller. The collector is of altogether novel construction. It is impossible to damage the battery by the hand resting between two pins, and the old objection of always using the first cells, and thus working these unduly, is entirely obviated. If preferred, however, the graduation may be obtained one cell at a time by altering the connecting cords from one screw terminal to another. The cords employed are of ordinary copper, were covered with gutta-percha, a supply of which is furnished with the battery.

The combined battery consists of a portable current battery, on the element board of which is fixed a coil worked by any number of the cells. The power is also graduated by a Rheostat. In this way the most delicate graduation of current possible is obtained from a weak battery-power to a strong one, and the Rheostat gives the finest effect possible of Faradism. These need no attention, are always ready for use, and will work the coil for many years.

Coxeter's instruments are so well known to the profession that we need only say that they were distinguished by the high degree of finish, neatness, and design, which has always characterised the productions of this firm.

Pratt, Oxford Street, had a very good show of the usual instruments required by the practitioner; we were particularly struck by the portable pocket-cases, eye, lithotomy, and operating cases. This firm has obtained many prizes, and the silver medal of the Cutler's Exhibition, 1879, was awarded for deformity instruments in connection with which Pratt has enjoyed a deservedly high reputation for many years.

Wright and Co., New Bond Street, showed a number of modern improved instruments, amongst which we may mention a very complete set of minor operating instruments in portable case, representing an ordinary travelling bag when closed, Benham's new steam antiseptic spray-producer, a portable set of uterine instruments.

Ladies with crooked noses may be interested in Adams' instrument with screw adjustment for forcibly adjusting the nasal septum. It seemed to us a very simple contrivance, and likely to effect an improvement.

Salt and Son, Birmingham, had a very elaborate assortment. This firm have distinguished themselves by the elegance of their designs in pocket-cases for small instruments, and for hypodermic syringes, and in a small glass case they had a collection of their gem productions, which were well worthy of inspection. Their large instruments for midwifery and lithotomy operations for all kinds were exceedingly well made and highly finished, and could vie with wares of the best London houses.

Arnold and Son, London, were as usual large exhibitors, and amongst their valuable assortment was particularly noticed their aspirators, hypodermic syringes, enema apparatus, gynæcological-cases and bags, all of which were beautifully finished.

They had several examples of their well-known constant current batteries, their vaporiser, bronchitis-kettle and combined inhaler, and several forms of stethoscope, single and double.

The bin-aural stethoscope is now coming into general use, and Arnold's specimens were very good. Their general stock of surgeon's requirements was well and carefully selected, and altogether their exhibit was one of the best in the museum. Arnold and Son are, we believe, the sole agents for Meyerstein flexible spray-producers.

On this stand was Buckston Browne's walking stick for the use of persons who have to practise self-catheterism, and also a small stand or chest of drawers for the same purpose. We have no doubt they will prove useful to old people.

Brill's microscopes attracted considerable attention as there were a large number on view, both single and binocular, especially adapted for the use of the general practitioner. These microscopes are so well known it is only necessary to allude to them.

Henry Crouch, Barbican, had also some microscopic slides and optical instruments, which were very good.

Pullan and Coney had an ophthalmic surgeon's test case, and wools for the determination of colour blindness.

Krohne and Seseman were well represented in the ophthalmic line, and their eye instruments attracted considerable attention. This house has made for itself a special reputation in this branch of surgical requirements, and we believe it still retains the character for which it has been noticed.

Hills' (Borough) stand was made up of the usual collection of surgical appliances, and their instruments seemed to us exceedingly well finished and designed.

Weiss and Co. had a large collection, including major and minor operating cases, eye and ear instruments, and other useful adjuncts to the armentaria of the surgeon. Their special cases are well made and arranged.

Meyer and Meltzer, who are old exhibitors, attracted numbers to their stall by a large display not only of novelties, but their standard productions, amongst which we may allude to their operating cases, their aspirators, midwifery instruments, and forceps.

We next allude to the operating chairs of T. C. McIlroy, 115 Charlotte Street, which included a novel post-morcem weighing table, specially designed at the request of the Surgeon-General of the United States Army, a surgical operating table, a gynæcological operating chair, an ophthalmic or ophthalmological chair, a self-adjusting invalid carrying chair, a fracture bedstead, a fracture extension appliance, an operating chair for the knee-chest position, and other appliances for the sick or operating room.

The Parkes' Museum lent a collection of orthopædic and deformity apparatuses of a very interesting character.

In our survey of the exhibition I think we have done justice to the exhibitors, and we believe our English instrument makers may fairly compare with those of any country. Next year we shall be able to put this to the test at the International Congress to be held in London in August, 1881, so that we hope that intending exhibitors will take special pains in producing good work as the credit of English manufacture will be at stake.

We must regard the annual museum this year as being a success, though we missed some well-known faces whom we hope to see next year.

Sir William Gull has devised a method of obtaining notoriety—viz., by always adopting some course of action of a singular nature, and not in accordance with the present usages of etiquette of the profession. We think we know of a better plan than his. The number of special instruments devised with the published names of the inventors, patentees, or designers is becoming great. It is the easiest and cheapest way of getting one's name advertised. The instrument maker does all this for you. He puts your name in the *Lancet* or *Medical Press and Circular*, and thousands to whom you were previously a nonentity become familiar with your name, and you become a household word. They ask for Binks's water-closet paper or Bolus's new improved seamless something, as advertised, and then you become associated in their mind with Laennec, Civial, Esmarch, Liebreich, and other really eminent men. One word to the wise. If you wish to obtain rapid notoriety, invent something, or if you cannot invent, borrow some one's invention, improve on it, alter the curve, shorten it, lengthen it, but do something by which you can advertise your name legitimately, and without violating the time-honoured customs of the profession. This is one lesson I draw from the excellent annual museum of the Cambridge meeting (1880) of the British Medical Association.

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Edinburgh 17, Bradford 17, Newcastle-upon-Tyne 18, Bristol 19, Sunderland 19, Glasgow 21, Wolverhampton 21, Oldham 21, Nottingham 22, Hull 23, Sheffield 23, Leicester 23, Portsmouth 23, Leeds 23, Plymouth 24, Birmingham 24, London 24, Norwich 24, Brighton 25, Liverpool 26, Manchester 28, Salford 31, and the highest rate 35 in Dublin 35.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 5½d

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
„ IF PAID IN ADVANCE . . 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C
A. H. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—
MACLACHLAN and STEWART, South Bridge, Edinburgh.
A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

UBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, six dollars (£1 3s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistancies, Vacancies, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, AUGUST 18, 1880.

THE LONDON WATER SUPPLY.

THE report of the Select Committee on the London Water Supply has at length appeared, and it is now finally settled that the Government will be no party to the purchase of the water companies at a price far beyond their value. As we pointed out months ago "the affairs of the companies were not, at the time Mr. Cross negotiated the purchase, sufficiently well known to enable a complete judgment of their value to be formed; and more than that, their future expectations were greatly over-estimated, and of this there can be no doubt whatever." During the past six months a good deal of light has been let into their affairs, nevertheless their market value at the present time with a far better knowledge of their condition is still many millions below the price which was to have been paid under the agreement. It was quite obvious also, as evidenced by the rise and fall in the market price of the shares that public opinion coincided with the opinion expressed on the transaction by the Corporation of the City of London and the Metropolitan Board of Works, namely, that the price offered in the agreements were greatly beyond the actual value of the property. The most ardent supporter of the companies has been unable to show that the total cost of the whole of the existing waterworks has much exceeded 12 millions; and of this sum the committee say "a considerable portion has been expended upon works which have already become useless or unnecessary."

But price is, after all, of secondary importance compared with the far more important question of public health, and for this reason we have to regret that the Committee bestowed apparently little attention upon whether it will not be far better to look for a better and new supply altogether. Nothing whatever is said either about the quality of the water, and it partakes very much of the nature of a quibble to say, "The Committee have not had before them any specific scheme for an independent supply, and that general speculations on the subject are of little value without detailed plans of the sources from which it is to be derived, and the cost of carrying it into effect." It has come to our knowledge that ample evidence was forthcoming on this point; indeed, that one or more feasible schemes with detailed plans and costs of every kind were offered to the Committee, but from some unaccountable cause, or other, best known to the Committee, it was determined not to receive evidence on this point, or enter upon the inquiry of a competing supply; every information was, however, offered to the Home Secretary, and ready to be placed before the Committee, on the question of a supply of pure water, and which could be obtained at a comparatively moderate cost from the Chiltern Ridge or from Watford. The abundance of the springs which overflow into the Colne Valley above Watford, and the purity of the water has long attracted the attention of all who take an interest in the supply of London with pure water. Robert Stephenson, forty years ago, pointed to the chalk hills around London as the great water-bearing strata, "charged with an enormous and inexhaustible quantity of water;" and further, "that it appeared to him scarcely possible to believe that anyone sincerely interested in the supply of the metropolis with pure water should hesitate to admit the fact." The cost of obtaining so desirable a supply has been fairly estimated by competent engineers, and it has been put at something like a third of the sum Mr. Cross proposed to pay for the present water supply. That Thames water, which, when its temperature rises to 60°, causes a large increase in the death-rate of London from summer cholera and other causes, should continue to be the beverage of four millions of human beings, is an almost incredible and inconceivable fact, especially so, when for nearly half a century men of science and eminent engineers have endeavoured to bring numberless Commissions and Select Committees to see that artesian wells sunk at Watford would send a sufficient and continuous supply of pure spring water to every part of London, at one-half the cost it now pays for water reported month by month "as containing deleterious organisations, and unfit for domestic uses."

THE MEDICAL PROFESSION AND THE HOMŒOPATHS.

IT was reasonable to anticipate that the unanimous reassertion by the Fellows of the Royal College of Surgeons

in Ireland, and subsequently by the Council of that College, of their opinion that homœopathy is a deception, and not to be tolerated amongst physicians and surgeons who have a regard for their professional characters, would create a buzz in the hive of the homœopaths, and that it has done so in reality those who choose to read the editorials of the current homœopathic journals may judge. The editors of those periodicals indulge themselves in a passion of angry scolding, in which they vituperate vigorously not only the Irish College of Surgeons, which adopted the vote, but the individual Fellows of that College who spoke in its favour; but they do not at all attempt to show cause why homœopathy should not be stigmatised as a deception unworthy of any gentleman's toleration. Their line of argument is that the members of the medical profession are illiberal because they taboo the professors of doctrines which they do not themselves agree with, and their accusation is that the medical profession does this because it is afraid of the success of homœopathy amongst the public, and therefore desires to stamp out homœopathy by any or every means.

To take first the motive which the homœopaths attribute to the medical profession, we can dispose of it in a sentence, by pointing out that in Ireland, at least, where the profession has declared its opinion most decisively and most recently, there is really nothing for the medical profession to be afraid of, homœopathy being hopelessly at a discount, and having made no progress at all during the present generation. There are in Ireland about 1,800 practising physicians and surgeons, amongst whom we know of only three professed homœopathic practitioners, and of these three gentlemen it may be said that they vegetate rather than grow. Is it likely that the presence of these three practitioners in Dublin, and of the small homœopathy-believing population who employ them, would move the Irish College of Surgeons to the paroxysm of jealousy and apprehension by which the homœopaths would have the public believe that the College is animated? We think not. In fact, we believe that the medical profession in Ireland is entirely indifferent to the presence of homœopathy amongst them, and would not think it necessary to notice the existence of any number of such practitioners who could ever hope to find a living in that country, because they know that the great bulk of the Irish people are incredulous respecting heterodox assertions, and that quackery has never found a fertile soil to the westward of St. George's Channel. All the fees which the medical profession in Ireland are likely to lose by the competition of homœopaths would not amount to more than a guinea out of the pocket of each physician or surgeon in the course of the year, and we therefore submit that the spokesmen for homœopathy ask their readers to believe too much when they require them to assume that the Fellows of the Royal College of Surgeons in Ireland are called to action by the peril in which their trade interests are placed by homœopathic successes.

But, on the other hand, the medical profession cannot afford altogether to ignore homœopathy, as some have recommended it to do. It may do so as long as that schism keeps itself aloof, and practises in its own way; but as soon as it begins to creep into public confidence by a display of its association with scientific medicine and surgery, it becomes necessary for the medical profession to sever such association, and to repudiate the connection, lest the public should assume that homœopathy is only a variation or an improvement on scientific medicine. It is because we see the necessity for keeping the line of demarcation wide and distinct that we have so cordially approved of the action of the Irish College of Surgeons, and so deeply regret the over-tolerance which the profession in England has extended towards homœopatic practice. If there were none others to be considered in the matter but the consultant who preferred illicit fees to his own character, and the homœopath who desired the professional support of such consultant, we need not condescend to notice the act of the member of our profession who would accept remuneration so earned. But it behoves the profession to allow the public no reason for believing that there is even a remote identity of homœopathy with the science which we practise, and it seems to us, therefore, that those who—like the Irish College of Surgeons—are entitled to speak on behalf of the profession are bound to assert that legitimate authority over practitioners who, for personal profit, help to impress the public with this belief.

But it is necessary to understand why the profession should be so anxious to keep the skirts of its robe clear of homœopathic contact. We have no desire to be offensive to practitioners of any sort, and we should be sorry to enter into a contest of expletives with the editors of the homœopathic journals, but it is impossible for us to make the attitude of the profession fairly understood without saying distinctly that it refuses any association with homœopaths, because it believes that the tenets of that schism—and more especially infinitesimalism—are not doctrines which may be honestly held by reasonable, thinking, and educated gentlemen; but are, on the contrary, theories put forward to attract the uninitiated and impressible section of the public. Of the doctrine of "*Similia similibus curantur*" we do not speak now, for, although with some knowledge of what has been written in its favour, we believe it to be unscientific, delusive and erroneous, we still can conceive a practitioner honestly holding it and acting upon it. But with regard to infinitesimalism, we cannot use any other phrase than to characterise it as a fraud to which no practitioner worthy of professional association should descend. We know, as a matter of fact, that very many homœopaths do not practise on such principle, and we have read the repudiation of it by some of the more honest writers on homœopathy, and we can see for ourselves that the enunciation of that dogma and its methods of practice are wholly repugnant to our sense of reason; and with every desire to take the broadest and most charitable view of the erratic ideas of individual practitioners, we really cannot coerce our intelligence to believe that homœopaths have any more real confidence in the dosology advocated in the homœopathic Koran than we have. We read, fresh from the pen of one of these editors who have attacked the Irish College of Surgeons, that infinitesimalism is not an essential of homœopathy. If not, we ask, why do homœopaths lead their patients to believe that it is? Do they not obtain the confidence of their clients by asserting that their practice is free from the danger of over physicking, and that medicine, as

usually practised, is ignorant, useless, and pernicious? If they were to let their patients know that they abandon their dogmas and their dosage when it suits them to do so, and fly to the erroneous and poisonous therapeutics of the average doctor, how many believers in homœopathy would remain at the end of the year? We say that a system supported by means of such dogmata or practices is unworthy of toleration, and unfit for the association of honourable gentlemen, and that it is rightly tabooed.

But suppose we and the whole profession are blind, ignorant, and wrong-headed; that fact does not alter our position. The legitimate surgeon and physician, rightly or wrongly, believes from the depths of his mind that black is black, and no other colour; the homœopathic practitioner is supposed to be equally positive that black is white. The life and health of the dying patient hangs upon the question upon which his two advisers are necessarily hopelessly at variance and incompatible. Can it, by any conceivable line of argument, be conceived honest or reputable for the physician to do violence to his whole teaching and his professed belief in order that he may fuse his practice with that which he confesses to be schismatic, erroneous and prejudicial to his patient? We say not, and we say that the surgeon or physician who violates his own earnest belief—be it false or true—in order to meet the tenets of his consultant, or the prejudices of his patient, does dishonour to his cloth, and deserves collegiate censure.

Notes on Current Topics.

Sir William Gull's Retractation.

Dr. Pavy's demand that Sir Wm. Gull should recall the utterances employed respecting the latter on the trial Regina *v.* Ingle, has elicited a reply which cannot be viewed in any other light than as an aggravation of the original offence. Sir Wm. Gull asserts that his statements were made "according to the convictions of his mind," and this being so it is pertinent to ask *how* these convictions arose. If the senior consulting officer of a charitable institution considers himself justified by his position alone, to rush to conclusions opposed to the deliberate judgment of his *working* colleagues, to whom, moreover, the actual collection of the data necessary to *any* decision falls, then it is high time an utterly false and unworthy use of authority comes to be recognised at its true value. Sir Wm. Gull deeply regrets "the necessity which obliged him to give expression to his opinion." This *necessity* is surely of his own creating; he could not be compelled to speak of anything, save what he knew *in fact*, even when under the inquisition of cross-examination, and it has yet to be shown that he was cognisant of any circumstance connected with the illness and death of Mrs. Morgan, save through report. It is strange, then, to read Sir Wm. Gull's excuse that "He could not in his evidence state what was right to the unfortunate nurse and fair for her defence, so far as it might go, without setting forth facts which seemed to show that there had been some misapprehension as to the nature of the symptoms of the disease under which the poor patient was suffering." The profession will wait with some impatience to learn by what occult agency Sir Wm. Gull could, without examination or even sight of a patient, arrive at conclusions concerning her physicial state strangely discordant with those described by her constant medical attendant, by one, too, so deservedly eminent as Dr. Pavy. Sir Wm. Gull is candid, though with a different intention, when he writes, "I could not read the facts as Dr. Pavy had done." Naturally this would be so, since Dr. Pavy read them direct from the body of "the poor patient" of Sir Wm. Gull's pitying commisseration, while the latter could read only their imperfect transcript as presented in a clinical report. The assumption, therefore, that he was obliged to state "his convictions," in court, "in the interests of justice," is surely a somewhat overstrained one, the more especially as this sacrifice to justice demanded the opposition of theoretical reasoning with actual experience. Taken altogether, Sir Wm. Gull's reply to Dr. Pavy lends only additional force to the requision for a judicial consideration of the conduct of the "senior consulting physician" to Guy's Hospital, by the Royal College of Physicians.

Expurgation of the Dental Register.

Our readers are no doubt aware that the British Dental Association is engaged actively in the effort to induce the General Medical Council to elide from the Dental Register persons who had obtained admission thereto as pharmaceutists, they not being legally recognisable as such. Our attention was last week called by Dr. F. T. Porter, of Dublin, to the fact that there are also a number of dentists who are inscribed on the Dental Register as "in the practice of dentistry in conjunction with" surgery or medicine, or both, although their names do not appear in the Medical Register. Of course the absence of the names of these gentlemen from the official list does not prove that they do not possess a registrable medico-chirurgical qualification, but we believe that the great majority of them do not possess any such qualification whatsoever; that they have been registered as dentists upon a false representation; and therefore, that their registration is invalid, and they are themselves liable to severe punishment.

We ask the attention of the British Dental Association to the matter, and suggest that, if these dentists have not been already included in the expurgation list, they ought to be added to it.

Educational Value of American Degrees.

Commenting on the fact that more than one-third of the candidates for the London College of Surgeons were rejected at its last examination, the *New York Medical Gazette* contrasts with this the fact that American medical colleges confer their degrees upon probably twenty-nine of every thirty of the applicants. Great Britain, says the *Gazette*, has never been a model worthy of imitation in this regard. The evil with us is ten or twenty fold greater; and if there are in this country any medical journals of real independence, it is their duty to speak, and never to cease their demand for reform until it is made. A leading New York newspaper lately said that it was hardly worth while to have so great a fuss about the Philadelphian bogus colleges, so long as all the medical colloges conferred

their degrees so indiscriminately. In the opinion of this Mr. White, our able Minister to Berlin, had been misled. It was not altogether because of the bogus Philadelphia colleges that American medical degrees had become a by-word in Germany.

The International Medical Congress.

THE work of organisation in the different sections in connection with the meeting of the International Medical Congress in London next year is being vigorously pushed forward; and on all hands the most cordial co-operation is being met with by the committee. A large number of foreign magnates eminent in medicine and surgery have signified their intention to be present at the demonstration, which promises to be the most brilliant ever made in connection with the profession. The expenses attending it will be necessarily large, and it is gratifying to know that subscriptions towards meeting them are fast coming in. The deep interest taken by the Queen and the Prince of Wales in the progress of research has been shown by the personal anxiety they have exhibited that the best possible arrangements may be made to ensure the perfect success of the meetings of the Congress.

Death of Professor Hebra.

DERMATOLOGISTS and the medical profession generally will learn with sincere regret, that the great master of that branch of practice dealing with skin diseases is now no more. Hebra, who has been made familiar to the English reader by the wise liberality of the New Sydenham Society in reproducing his great "Atlas," placed the study of dermatology on a secure footing, by arranging a classification of the diseases of the skin, that has been the basis of all subsequent work in the same direction. His bright example has, however, stimulated a small army of specialists who are following worthily in the footsteps of their great leader, and we in England can reckon more than one who, while counting as disciples, are yet co-equal with Hebra in the magnitude of their contributions to dermatological science. It is they who will feel his death; it is these and others with them, also, who can effect that his loss will not result in injury to the pursuit he so fondly cherished.

Detection of Sewer Gas.

AT the meeting of the British Medical Association at Cambridge, Mr. Jabez Hogg, in the section of Public Medicine, exhibited and described a perfectly new and very ingenious instrument for detecting sewer gas, and fire and choke damp in mines. The action of the instrument is founded on the law of diffusion. Gases, as is well known, have the power of diffusing or becoming intimately mixed together even when differing in specific gravity. They do not, however, combine chemically, and the rate at which they diffuse varies considerably, but diffusion is apparently promoted by interposing a thin porous tile. Experimental research has shown that the velocity of diffusion of gases is precisely proportional to the square roots of their densities. Thus four volumes of hydrogen will pass through a person's diaphragm in the same time that a volume of oxygen will, oxygen being sixteen times as heavy as hydrogen. This remarkable property of gases has an important bearing on the atmosphere of our towns, and purifying the air of our houses. By the invisible agency of diffusion the air is changed and rendered more wholesome than it would be were there no such law in action. This being a settled fact, and the rate at which diffusion takes place being experimentally ascertained, it but required the aid of an instrument which might be relied upon to measure and indicate the same, as the aneroid barometer marks and denotes the variations of air pressure. The "Sewer Gas Detector and Fire Damp Indicator" shown by Mr. Jabez Hogg, fairly solves the problem. The form of the instrument is that of the aneroid barometer, the rigid brass back being removed, and is replaced by a piece of porous tile, of the ordinary Wedgewood biscuit ware. This, together with some changes in the mechanical arrangements of the instrument, appears to be all that is necessary. When a detector, so constructed, is brought into an atmosphere charged with fire damp, sewer gas, or other kind of gas, the gaseous atoms instantly diffuse into the inner closed-up chamber with much greater rapidity than the atmospheric air passes out. This causes pressure to be made upon a spring in connection with an index hand, when it is seen to move over the graduated dial face. In the case of its being brought into an atmosphere charged with a heavier gas than common air, as choke damp, or carbonic acid gas, diffusion causes the vacuum chamber to expand, and then the hand drops, or moves in the reverse direction. To restore the equilibrium of the instrument it is necessary to turn a small stop-cock at the side of the instrument, which lets in the atmospheric air, and immediately brings the index hand back to zero. The dial face is graduated to a scale, and correctly marks the non-explosive, the explosive, and the very explosive nature of the mixed gases. The nature of the gas escaping from a sewer, or a leakage of gas of any other kind, is as exactly indicated. In round numbers 1 per cent. of gas is found to be equal to ·01 inch, and 10 per cent. of gas to 10 on the aneroid barometer. This gas detector is found equally serviceable for the detection of gaseous exhalations of all kinds, whether they be light or heavy. It will be found as serviceable and useful in mines, and in subterranean works of other kinds. In the sinking of wells, in breweries, in street subways, in holds of ships, where dangerous gas accumulations often take place, in escape of gas in houses, in public buildings, in testing street gas pipes, and in tracing an escape of sewer gas. The instrument is so little likely to be deranged in action, and so simple in its application, that it may be placed in the hands of those quite unacquainted with the use of a scientific instrument, so that whether it be employed by the officer of health, the sanitary inquirer, or the inspector of nuisances, the result will be equally happy.

Mr. Jabez Hogg concluded by expressing his great indebtedness to Mr. F. Ansell, to whose scientific skill he was so much indebted for the perfect and beautiful instrument he was enabled to place before the section.

International Congress of Laryngology.

THE extent to which the study and practice of diseases of the larynx and adjacent regions has grown is shown by the increased recognition which it is daily receiving in all parts of the Continent. Arrangements are now in progress for the holding of an International Laryngological Congress at Milan, from the 2nd to the 5th of September of the present year. The committee of promotion, by whom the circular respecting the meeting is signed, consists of Drs. Labus, Elsberg, Krishaber, and Stoerk; and the secretary is Dr. Frua. In the discussions the French language will be that adopted, but communications may be made in any tongue. Several important communications have been already promised by the leading laryngologists of England, France, Germany, America, Italy, Belgium, and Spain. Among those who have promised communications are Dr. Mandl of Paris, "Sur la Voix des Mammiferes;" Dr. Heinze of Leipzig, "Ueber eine seltener form von Larynxstenose;" Mr. Lennox Browne of London, (1) "On some Objective Evidences associated with the Condition known as Globus Hystericus;" (2) "On Buccal, Lingual, and Pharyngeal Tuberculosis;" (3) "Three Cases of Lupus of the Larynx;" Dr. Krishaber of Paris, (1) "Du Spasme de la Glotte dans l'Ataxie Locomotrice; (2) "Récherches Experimentales sur l'Intensité de la Voix;" (3) "De la Laryngotomie inter Cricothyroidienne;" Dr. Bristowe of London, "On Pressure on the Trachea and Recurrent Laryngeal Nerve and their Effect;" Dr. Thaon of Nice, "L'Hysterie et le Larynx;" Dr. Labus of Milan, "De l'Influence du Relachement de la Luette sur la Voix;" Dr. Porter of St. Louis, "Excision of the Epiglottis;" Dr. Zawerthal of Rome, (1) "Sulla Rino-Laryngorrea Cronica;" (2) "I Carratteri Clinico-Anatomici della Tubercolosi Faringea;" Dr. Schnitzler of Vienna, "Ueber Kehlkopfschwindsucht." Many other papers are announced, and the subjects of Laryngeal Phthisis and Syphilis will be treated upon by such authorities as Dr. Schmidt of Frankfort, Dr. Heinze of Leipzig, Dr. Ariza of Madrid, &c., &c. From such a meeting much advance in the science of laryngology may be expected. We commend the congress to the attention of those of our readers interested in throat affections, and heartily wish it success. It is to be hoped that next year the Congress may be held in London concurrently with the meeting of the International Medical Congress.

The Treatment of Pneumonia by Digitalis and Alcohol.

DR. ALBERT JOLY (*Le Praticien*) records the results obtained by Dr. Alix at the military hospital of Toulouse, by the use of digitalis and alcohol in the treatment of acute pneumonia. The conclusions are as follows:—1. Simple or double, free pneumonia is but little serious unless we obstruct its normal evolution and natural tendency to cure by untimely medication. 2. Its affinity to the eruptive fevers (internal herpes of some authors) seemed to be confirmed by this regular progress. 3. Pneumonia is essentially a weakening affection, in which the temperature descends below the normal, more than in any other inflammatory disease. It is evident that the principal indication is to combat the debility and raise the organism again by excitants, especially alcohol, which is to some extent a food. Nevertheless, since temperature simply by its elevation often constitutes a danger, it is important to prevent it, not by bleeding, or tartar emetic, but by digitalis, the happy effects of which are undeniable. 4. Every new cause of increased temperature should be carefully warded off at once, and therefore blistering should not be used, since by the wounds it produces and the accidents it causes it notably raises the temperature. 5. The exudative pulmonary congestion, which by its abundance creates permanent danger, must be carefully warded off. Hence opium, which favours it, must be cautiously given. Blistering also must be avoided on this account, since by rendering the chest motionless it makes expectoration difficult.

Health of Hastings.

THE report of the medical officer of health for the quarter ending June the 30th last, in the municipal borough of Hastings, gives a birth-rate of 28·98 per 1,000. The deaths in the quarter numbered 194, giving a rate of 19·50. Thirty-two of these were visitors, and the total also includes those who died in public institutions. Zymotic diseases caused 33 deaths, not less than 28 being from measles; 1 death from croup, 3 from whooping-cough, and 1 from enteric fever. Constitutional diseases, as usual, chiefly augmented by phthisis, 31—of these 13 were visitors. Local diseases caused 92 deaths, of whom 17 were visitors. There have been very few applications for sanitary measures, or reports of nuisances, &c., during the quarter, and the different parts of the borough, which have been inspected, have not called for special remark—the sanitary conditions of most of the poorer properties having been considerably improved upon latterly. Six samples of milk were analysed, and one sample of whisky. The latter was pure; three of the milk samples were genuine, and the remainder were either of poor quality or adulterated with a small percentage of water.

The Treatment of Perspiration of the Feet.

DR. ORTEGA (*Le Praticien*) advocates the use of a solution of chloral in this affection. A patient of his, a strong man working in an ice manufactory, suffered from it in an extreme degree—so much so that his fellow-workmen would not work by his side. The epidermis of the sole of the feet was white, as if macerated; there were small ulcerations in the furrows, and also around the nails. The odour was overpowering. Dr. Ortega prescribed baths of a solution of chloral—1 in 50—and wrapping the feet in a cloth dipped in a similar solution. Two days after the smell had disappeared. Six days later, the treatment being continued, the ulcerations were less moist and covered with a layer of epidermis.

A Simple Treatment of Ozæna.

ANY simple treatment which is efficacious in so troublesome a complaint as ozæna is a desideratum. Dr. Gottstein (*Berlin Klin.*) believes that ozæna is due not to congenital narrowing of the nasal fossæ, but to their being too wide. The current of expired air loses its force and becomes powerless to remove the products of secretion, which, being retained, become fœtid. The author has

always found a condition of atrophy and anæmia of the mucous membrane of the turbinated bones in ozæna. He has always found advantage in plugging the nostrils with cotton wool so as to allow the passage of air. Under the influence of this plugging the mucous membrane resumes its vitality, the secretions become normal again, and the ozæna is cured.

Bromide of Potassium Spray in Whooping-Cough.

The good effects of bromide of potassium in the treatment of whooping-cough are well known to all practitioners. According to Dr. Wintreben (*La France Médicale*) the action of this remedy may be made still more efficacious by bringing it in contact with the mucous membrane of the air passages in the form of spray. The author habitually uses a solution of bromide of potassium, one in twenty, and repeats the application of the spray for one minute after each fit of coughing, when the mucous membrane of the breath passages, free from the mucus which usually covers it, is accessible to the action of the remedy.

The Library of the Royal Medical and Chirurgical Society was closed on Monday, August 16th, and will be re-opened on Thursday, Sept. 16th next.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 16, Bombay 28, Madras 31; Paris 29; Geneva 15; Amsterdam 24, Rotterdam 21, The Hague 23; Copenhagen 28; Stockholm 31; Christiania 24; St. Petersburgh 49; Berlin 47, Hamburg 23, Dresden 32, Munich 38; Vienna 27, Buda-Pesth 45; Rome 27, Turin 25; Venice 35; New York 40, Brooklyn 35, Philadelphia 28, and Baltimore 19 per 1,000 of the population.

The death-rate from the seven principal zymotic diseases per 1,000 last week in the large towns ranged from 3·5 and 3·7 in Newcastle-upon-Tyne and Bristol, to 10·0 and 12·1 in Leicester and Salford. Scarlet fever showed the largest proportional fatality in Norwich, Salford, and Sunderland; and whooping-cough in Liverpool. Small-pox caused 2 deaths in London, 6 in Dublin, but not one in any of the other large towns. The deaths referred to diarrhœa in these towns, which had steadily increased from 51 to 577 in the seven preceding weeks, further rose to 711 last week.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

The Late Dr. Mackie, Cupar.—The estate of the late Dr. Mackie, Cupar, is sworn at £17,424.

Ayr Hospital.—The sum subscribed for Ayr New Hospital up to the present time is £3,120. The estimated sum necessary to complete the institution is between £5,000 and £6,000.

Combe Lectures on Physiology and Health.—The trustees of the late George Combe have made arrangements to utilise a portion of the funds at their disposal in accordance with the disposition of Mr. Combe, for the diffusion of a knowledge of physiology and the laws of health in large provincia towns and manufacturing centres, during the ensuing winter and spring. The trustees appointed Dr. Andrew Wilson, F.R.S. Ed., as the "Combe Lecturer," and that gentleman, whose experience as a lecturer will be of great value in connection with the aims of the trustees, has been engaged in arranging for courses of lectures to be delivered in Kirkcaldy, Dunfermline, Stirling, and Dundee. In each of these towns a local committee of influential gentlemen has been formed to make the necessary arrangements for the forthcoming winter and spring lectures, the trustees bearing all expense connected with the lectures, apparatus, &c. The lectures will number from eight to ten in each town, and will be delivered once a week in the evening. From the interesting nature of the subject, and from the importance to all classes in a sanitary and education point of view, there can be little doubt that the movement thus inaugurated by the Combe trustees will arouse a large share of public attention. Applications for the Combe Lectures have been received from other towns than the four just mentioned. Part of the work sketched out by the trustees includes the delivery by Dr. Wilson, of lectures to the students of the Church of Scotland Training Colleges in Edinburgh and Glasgow.

The Late Dr. Greig, Fyvie.—It has been resolved to take steps for commemorating the memory of the late Dr. Greig, Fyvie, either by the founding of a medical bursary, or by erecting a memorial stone over his grave. A large committee has been appointed to do what is necessary in the matter.

Health of Hillhead.—The medical officer's report for July, 1880, shows that during the month there were registered 18 births, and 2 deaths, representing an annual birth-rate of 30·85, and a death-rate of 3·43 per 1,000 of estimated population.

Death from an Overdose of Laudanum.—A grocer, named Walter Graham Scott, died in the Edinburgh Royal Infirmary on Saturday, the 7th inst., from the effects of an overdose of laudanum. Deceased had been ailing for some time, and had been advised by a friend to take a little laudanum to relieve his pain, but the man unfortunately swallowed too much.

Mortality of Kirkintilloch.—The medical report for July, for this burgh, shows the total deaths within the burgh as 4, equal to a death-rate for the month of 6·8 per 1,000 per annum, being the lowest death-rate for any month for the past three years.

Registrar-General's Returns.—According to the weekly return of births, deaths, and marriages for the eight principal towns of Scotland, the death-rate for the week ending with Saturday, the 7th of August, 1880, was 19·8 per 1,000 of estimated population. This rate is 3·2 above that for the corresponding week of last year, and 1·4 above that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 15·6 per 1,000; and the highest in Paisley, viz., 38·2 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 5·0 per 1,000, being 0·3 above that for the last week. The increase was principally due to the number of deaths from diarrhœa in Glasgow. Acute diseases of the chest caused 67 deaths, being 8 more than the number for the previous week.

Literature.

THE HEART. (a)

THESE contributions to the subject of cardiac pathology we have classed together, being somewhat at a loss to understand why they were issued separately within a month of each other, and as the subjects of the two essays are part and parcel of the diseases of the one organ.

Notwithstanding all the attention which has been given to diseases of the heart, and the many works which have recently been written on the subject, it must still be allowed that there are many points which are open to discussion. What is the cause of this? Or why is it that such direct differences of opinion, we might almost say, still exist? It is in part to answer such questions that it seems to us the author has applied himself in the essays before us. For we observe that all the topics which he discusses are amongst the disputed questions which relate to diseases of the heart. Thus we have chapters on "The Second Sound and Murmur of the Heart in their Relation to Diagnosis," and again on "Murmur in the Pulmonary Artery," and so on. For ourselves it does not appear at all strange that these special subjects still require much investigation. They will continue to do so, we believe, till the physiology of the organ is absolutely cleared up. Do we yet know all the causes which go to produce the two sounds of the heart? Are the various causes which modify the sounds completely ascertained? We think not. We also consider, too, that though the orifices are in one sense quite distinct, they are yet sufficiently close to be modified, the one by the other. As an example of what we mean, we might instance the case of diseases of the aortic valves, and this seems to be a favourite subject with our author. Now here, whilst the valvular disease will cause a morbid sound or sounds, it seems to us impossible but that these sounds must be modified by the healthy sounds in the pulmonary artery, which we know are so very close. It is true the aortic orifice is nearest the ear, but we are not, therefore, to ignore the sounds which are produced in the mouth of the pulmonary artery, and which must reach the ear. Whether this view of the subject has been advanced by others we do not know; but we firmly believe that it is capable of modifying the morbid sounds which so often exist in the mouth of the aorta. Something of the same kind, too, occurs in cases of pericarditis, where a bruit de soufflet and frottement are, as we know, often so mixed up that it seems impossible to say which is which. Yet these are sounds produced by totally different causes, and, *à priori*, we would expect they could be distinguished one from the other. We believe the explanation given above is the main cause of these difficulties; and that they will continue to exist, at least till the physiology of the organ is indisputably established.

The remarks just made are fully borne out when we come to read the special chapters of the little volume we have placed at the head of this article. The first is on the "Second Sound and Murmur of the Heart in relation to Diagnosis." In commencing it the author premises a few observations on the impulse, rhythm, and sounds of the heart, and it is scarcely going too far to say that on the causes of each of these he speaks in doubtful terms. How is it possible, in view of such statements, that any definite conclusions can be arrived at in relation with morbid sounds or movements in the heart? Here we have a gentleman who has evidently given much attention to the subject, and is quite familiar with the latest teachings on the physiology of the heart, and yet we repeat that the conclusions are indefinite and vague. We do not say this with any idea whatever of blame, but simply to show what difficulties yet beset the path of cardiac pathology.

In this first chapter there are, we notice, two points which call for remark. The first is that the author questions the frequency of the greater accentuation of the second sound. Not that he denies its occasional presence; but that it is not at all so frequently present as many writers of the present day allege. For ourselves we rather side with the author, but the point is one requiring still more investigation. When a morbid sound has to be determined on solely by a difference in degree—not in kind—we need scarcely say that the greatest caution is requisite in arriving at a definite conclusion; and this is the case here. In the second place the author states his belief that causes for the occurrence of a bruit on the right side of the heart are more common than is usually thought. If we assume this to be correct—though having doubts of it ourselves—it only adds to the difficulties which surround the subject. One other point which the author notices in this chapter; we speak of the reduplication of the second sound. The author does not give us any reason for this phenomenon. We have observed it ourselves in a very marked form, and think that it is most likely due to a very slight impairment of either the pulmonary or aortic valves, and that a still more advanced alteration in the valves would probably produce a soufflet. Skoda holds a somewhat similar view. We have heard it louder at the base of the heart; but the author gives cases where it existed at the apex.

The second chapter is taken up with a consideration of the subjects which have been already named; we mean "Diseases of the Right Orifices of the Heart." This is an interesting chapter. There are two cases given, with the result of the post-mortem in each, and in which the diagnosis of disease on the right side was made during life, and confirmed after death. The author observes that in each there also existed tuberculous disease of the lungs, which, on the left side, had a tendency to have the pulmonary artery uncovered, and so the morbid sounds which existed were clearer than they would otherwise have been. In one of the cases especially the amount of hypertrophy of the right ventricle was very considerable. The author makes the important statement that he believes disease of the right heart leads to phthisis.

The third chapter is taken up with the minute details of a "Case of Persistent Murmur in the Pulmonary Artery." It is a case of much interest, and we think the writer has made out a fair solution of it, though in the absence of a post-mortem—for the patient still lives—the absolute proof is wanting. This disease of the pulmonary valves the author also considers of greater frequency than is usually supposed, and we must say that the statistics he adduces confirm the opinion. Thus, as one example, he gives 41 cases of valvular disease collected by Peacock, of which 32 affected the left side, and no less than 9 the pulmonary artery. This nearly gives one case in every four; but the cases may have been exceptional, and they far exceed our own personal observation. As to the case detailed, if we would venture a conjecture, it would be as to the possibility of the pulmonary artery being narrowed; we mean congenitally. Such cases are not very uncommon, and in this particular instance all the symptoms present could be explained by this state. It would explain, too, the persistent murmur without there being any disease of the valves, and also the lung symptoms which were present. If we mistake not, there are cases on record which would bear out these remarks, but we could not lay our hands on them just at present. We observe the author speaks of the ductus arteriosus being open, and at the same time imperfection of the mouth of the pulmonary artery, as states which might explain the symptoms present in the case. We still consider, however, the congenital narrowing of the pulmonary artery is as likely to be the state of the parts as any other advanced.

Our space prevents us noticing the subjects of the fourth and fifth chapters, which treat respectively of "Additional Observations on Transposition of the Great Vessels of the Heart," and "Further Notes on Pulsatory Tumours of the Neck." But the last chapter in the book being on the same subject as that treated in the second essay, we must briefly notice. It is "On Insufficiency of the Aortic Valves in connection with Sudden Death." After giving a sketch of the literature of the disease from the time of Harvey forwards, and quoting the names of Hunter, Burns, Stott, Bertin, Hodgkin, Hope, and Corrigan, to the last of which he gives the credit of being "the discoverer of the malady," he then goes on to state his own views, and specially on the point of sudden death, which he considers as of much more

---

(a) "Contributions to Cardiac Pathology." By John Cockle, A.M., M.D., Fellow of the Royal College of Physicians; President of the Medical Society of London; Physician to the Royal Free Hospital, &c. London: Baillière, Tindall, and Cox. 1880. Pp. 85.

"On Insufficiency of the Aortic Valves in connection with Sudden Death." With Notes Historical and Critical. By John Cockle, A.M., M.D. Pp. 64. Second Edition. London: Baillière, Tindall, and Cox. 1880.

moment than is usually supposed in the affection. We must be allowed to question this view. Not that sudden death is unknown, for this would be contrary to fact; but that it is so rare—at least, in our experience—as scarcely to come within the range of the modes by which life may be terminated. We could have wished that the author had given us some examples of the sudden death. For ourselves we believe that its great rarity is due to the nature of the valvular lesions present, for as soon as the valve or valves become diseased the heart begins to take on a compensatory action, which, in a degree at least, antagonises the bad results of the valvular lesion; and we know, as a matter of experience, that in cases of this kind life may be, and has been, prolonged for years, and to this point the author very properly alludes. But to return to the question of sudden death when insufficiency of the aortic valves exists, we believe that other causes must be present to cause it. Foremost amongst these is degeneration of the muscular texture, which is known to be a frequent occurrence. Now when such a combination exists, and sudden death occurs, are we to attribute the event to the state of the valves? We think not; but much rather to the state of the muscle, which we know, without any valvular disease, frequently leads to sudden death. With our present experience we consider this a much more plausible explanation of the sudden death than what the author has advanced. Adherent pericardium is a second and common complication of aortic valvular disease. But here also degeneration is common, and would be, if not the sole cause of sudden death, at least the leading one. Exactly similar remarks might be made of disease of the left auriculo-ventricular opening, where sudden death, as far as we have seen, only occurs where degeneration exists. The point discussed is one of considerable moment, and we think the author quite right in drawing attention to it, though we differ from him in our views on the subject.

In concluding our notice of these two essays we feel bound to recommend them to our readers. They will find much to interest them in each chapter; and though not suited for beginners, they are not the less valuable on that account.

THE ANATOMY OF THE JOINTS OF MAN. (a)

A Thorough systematic work on the joints has long been a much-felt want, which Mr. Morris has boldly attempted to supply by the volume before us, and he has certainly succeeded. Unfortunately the study of articulation is perhaps the most unpopular part of anatomy with the greater number of students, and it is only quite a limited number that leave our schools with a good knowledge of them. Even the frequency and importance of joint diseases has failed to attract attention to the structure and peculiarities of the joints. It is difficult to account for this. It is partly the result of the "unpopularity" of the joints; but no doubt some of the blame must be at the door of the anatomical teachers and authors who have neglected to devote sufficient care to this important part of their work. Mr. Morris's book treats of all the different structures met with in the joints in a very thorough, precise, and careful manner; and although he mainly follows the descriptions of others, he has yet made each joint a special personal study, and has been able to correct so amply what has hitherto been wrong or scanty in their descriptions. His opening chapter on the general structure and classification of articulations is not so good as the rest of the book, it is verbose and at the same time deficient in some points, and it retains an old and useless classification. In the chapters on the separate joints separate descriptions are given of the bones, ligaments, fibro-cartilages, synovial membrane and appendages, bursæ, vessels and nerves of supply, uses, and muscles acting upon them. Here we cannot complain of any lack of detail—indeed, some may find the descriptions even too minute. The style is pleasant and clear on the whole, but, like so many writers, Mr. Morris is constantly irritating the reader by the use of "former" and "latter," which almost always necessitates a reference to the preceding sentence. The engravings are most of them original and on the whole good; but why so good a book should have been disfigured by several ugly valueless chromo-lithographs is to us a mystery. We hope that when another edition is called for, as it assuredly will be, these illustrations will be omitted. More accurate plates of the bursæ might also with advantage be introduced. But these, after all, are but minor defects in a very good and much-needed book.

(a) "The Anatomy of the Joints of Man." By Henry Morris, M.A., M.B. Lond., F.R.C.S., Senior Assistant Surgeon to, and Lecturer on Anatomy and Demonstrator of Operative Surgery at, Middlesex Hospital. London: J. & A. Churchill. 1879.

Correspondence.

SIR WILLIAM GULL AND THE SCANDAL AT GUY'S.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Perhaps in your anxiety not to press unduly upon Sir William Gull you have, in your comments on the above matter, omitted to mention some facts of the case which are of material importance. You have not stated that Sir W. Gull was not by any means bound to give evidence in the case at all. He was not a witness as to fact; he had not seen the patient; nor had he any personal concern with her case. He appeared merely as an expert, to give an opinion upon the evidence of Dr. Pavy and the other medical witnesses, as tendered in court. No one can doubt that it was Sir W. Gull's duty to have refused to enter the witness-box, even were he pressed to do so, and it was quite in his power to so refuse. He must have either volunteered as a witness, or yielded to the invitation of those conducting the prisoner's defence—for they had no power to subpœna him—and in this light his conduct becomes the more inexplicable. One would have supposed that in reply to a solicitation to pronounce an opinion on the case he would have pointed out that such an opinion must be practically valueless—mere hypothesis, based upon insufficient hearsay evidence, and not to be weighed against the deliberate judgment of Dr. Pavy, who was fully acquainted, from personal observation, with all the clinical facts, and had, moreover, the advantage of a post-mortem examination to confirm his interpretation of the pathological events. That the evidence derived from the autopsy would be of the utmost value, and that it was ably made out was sufficiently proved by the fact that the well-known officers of Guy's, including, Dr. Mahomed, were engaged in this work.

One thing is certain—that until occurrences of this kind become impossible, in consequence of the existence of a higher tone of gentlemanly feeling among all the so-called leaders of the profession, it is hopeless to expect that the profession will attain to that position of public respect and esteem to which the personal qualities and scientific attainments of the majority of its members so fully entitle it.

Yours faithfully,

H. S.

NOCTURNAL ENURESIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It will oblige me greatly if you will kindly insert this note in your next issue, as I am most anxious to get information either from yourself or from some of your numerous readers on the subject it refers to. A gentleman, aged about 45, has for the last six or seven years suffered from the most unpleasant and disagreeable annoyance of his urine coming away involuntarily at night. *During the day, and while he is awake* no water comes away, and he has full control over the bladder; but immediately *sleep takes place*, notwithstanding every precaution has been taken to empty the bladder previously, the water commences to flow and wet the bed. It is a most disagreeable affection and almost causes the gentleman's life to be miserable, as he cannot visit from home or go into a strange bed. The quantity and quality of the urine are healthy and normal. Could anything be done or any treatment suggested to remove the complaint?

Your obedient servant,

A Subscriber to the M. P. & C.

August 3rd, 1880.

INDIAN MEDICAL ITEMS.

MEDICAL OFFICERS OF CANDAHAR FORCE.—The name of Dr. Preston appears in the list of wounded at Kushk-i-Nakhud. Dr. Edge and Dr. Earle are among the missing of General Burrows' force.

THE *Indian Medical Gazette* has learnt from several sources that the increase of the scale of pensions is a mere question of time; that the question is under the consideration of the Secretary of State, and that an early and favourable isuse of orders on the subject may be expected.

INDIAN MEDICAL SERVICE.—Surgeon-Major R. Bowman is appointed to medical charge of political agency, Turkish Arabia. Surgeon-Major D. F. Keegan to medical charge of 1st Central India Horse. Surgeon R. Caldante, the 2nd Central India Horse, Western Malwa Agency, and Station of Ag. Surgeon H. Wortabet, from 2nd Madras N. I. to Peshawur.

CASUALTIES IN AFGHANISTAN.—A return has been made to the House of Commons of the numbers killed or dead of disease or invalided in each of the three armies operating beyond the Indus in the late campaign in Afghanistan (1878-79), from the date of advance beyond our frontier into the Khyber Pass up to the return across the Indus of the regiments ordered back at the close of the operations in the field. The numbers are given per regiment, troop, and battery, and the casualties of the three armies appear separately. The abstract at the close shows that eight European and two native officers were killed in action, and two European officers died of their wounds; 14 European and 21 native officers died of disease; 62 European and 43 native officers were invalided, Total casualties among officers—Europeans, 86; natives, 66. Among the British troops 17 men were killed in action, 3 died of their wounds, 315 of disease, and 1,176 were invalided—total, 1,151. Among the native troops 75 were killed in action, 23 died of their wounds, 1,129 of disease, and 1,586 were invalided—total, 2,813. The grand total of casualties among men was thus 4,324: including officers too, 4,476.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

AN EYE-WITNESS.—Letter received. We cannot deal with it until the whole of the facts are in our possession. We shall be glad to have all the information our correspondent can afford—in confidence—and will then investigate the matter thoroughly.

DISPENSARY RESIDENCES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Please inform me in your next issue what steps I am to take in order to get a residence built under Mr. Bruen's Act? The lord of the soil is prepared to give the ground for such purpose at a low rent. The Guardians of this Union were opposed to the passing of the Act in question, and consequently it may be difficult to get their sanction. On what terms can they borrow the money, and from whom? What time will it take to pay off the sum borrowed? The landlord will give a lease of ninety years. After the principal is paid off will the house become the property of the Guardians, minus the ground-rent? Can they charge the medical officer a higher rent than will pay the ground-rent and interest?

By answering the foregoing in your next issue you will much oblige,

Yours, &c.,

"A CONSTANT SUBSCRIBER."

[The Act will be found in the "Irish Med. Directory" for 1880, page 93. The steps necessary to be taken are—1. Owner must obtain from the Secretary of the Local Government Board a certificate that a dispensary house is needed in the district, and that the house proposed to be erected is suitable. Before granting such certificate, plans and specifications must be laid before the Local Government Board, and an inquiry held if necessary. 2. Such certificate having been obtained, an application for the money must be made to the board of works, and the certificate sent in. 3. If they agree to grant a loan, it must be repaid at the rate of 5 per cent. in each year for 35 years, and be subject to 3½ per cent. interest. 4. Guardians may agree with the owner for a lease and for a rent, and the said rent may be deducted from the salary of the medical officer.—ED.]

METRIC EQUIVALENTS FOR AVERAGE DOSES OF SOME MEDICINES COMMONLY USED.

VACANCIES.

Brighton and Hove Lying-in Institution.—House Surgeon. Salary, £120, with furnished apartments. Applications to the Secretary before Aug. 31.

Children's Hospital, Birmingham.—Assistant Resident Medical Officer. Salary, £40, with board, &c. Applications to the Secretary not later than Sept. 1.

Herefordshire.—Medical Officer of Health for the Rural Sanitary Authorities. Salary, £500. Applications to the Clerk of the Committee on or before Aug. 25.

North Eastern Hospital for Children.—House Surgeon. Salary, £70, with board and lodgings. Also a Registrar. Salary, £50. Applications to the Secretary not later than Sept. 1.

APPOINTMENTS.

BERKART, Dr. J. B., Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

BOVILL, Mr., House Surgeon at Guy's Hospital.

CROOK, Mr. J. S., House Surgeon at Guy's Hospital.

CROSSLEY, J. P., L.R.C.P.Ed., L.F.P.S.G., Medical Officer to the Workhouse of the Sunderland Union.

ERSKINE, J., M.D., L.R.C.S.I., Medical Officer to the South-West District of the Parish of St. Luke's, Chelsea.

HEATH, R. E., Honorary Surgeon to the Torbay Hospital, Torquay.

JOHNSTONE, J. C., M.D., C.M., Assistant Physician to the Royal Edinburgh Asylum, Morningside.

KIDD, P., M.A., M.B., M.R.C.P.L., Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

KIDD, P. H., M.B., C.M., Junior House Surgeon to the Carlisle Dispensary.

LANE, Mr. W. A., House Physician at Guy's Hospital.

LEDIARD, H. A., M.D., F.R.C.S., Surgeon to the Cumberland Infirmary.

MORGAN, Dr. W., Public Analyst for the County of Glamorgan.

POLLARD, W., F.R.C.S.E., Consulting Surgeon to the Torbay Hospital, Torquay.

RAKE, Mr. B. N., House Physician at Guy's Hospital.

SCOTT, Mr. A., House Physician at Guy's Hospital.

SMITH, W. F. F., M.B., C.M., Medical Officer to the Wildon District of the Orsett Union.

STREET, A. F., M.A., M.B., M.R.C.S.E., House Surgeon at the Royal Infirmary, Manchester.

WATTIE, A., M.A., M.B., C.M., Assistant Medical Officer to the Crumpsall Workhouse, Manchester.

WHITE, Mr. W. H., House Surgeon at Guy's Hospital.

WILMOT, T., L.R.C.P.L., M.R.C.S.E., L.S.A.L., House Surgeon to the Bradford Infirmary.

Births.

DAY.—Aug. 3, at Clayton House. Chapel Street, Pentonville, N., the wife of W. Henry Day, L.R.C.P., of a daughter.

THOMPSON.—Aug. 8, at Cranley Place, South Kensington, the wife of R. E. Thompson, M.D., of a son.

Deaths.

BEVAN.—Aug. 1, at Rickinghall, Suffolk, T. K. Bevan, M.D., son of the late Venerable Archdeacon Bevan, Vicar of Carmarthen.

DRYSDALE.—Aug. 7, at Hillend, Linlithgowshire, John Drysdale, M.B., L.R.C.S.E., F.R.P.S.E., late of Uphall.

Abstract

OF THE

ADDRESS IN MEDICINE,

Delivered at the Meeting of the British Medical Association at Cambridge.

By JOHN BUCKLEY BRADBURY, M.D., F.R.C.P.,

Physician to Addenbrooke's Hospital, Cambridge; Linacre Lecturer in Physic; Medical Lecturer in Gonville and Caius College; and Assessor to the Regius Professor of Physic in the University of Cambridge.

Dr. BRADBURY's address was devoted to a *résumé* of the discoveries made within recent years by instrumental aid. By the aid of the microscope, he said, an advance has been made in the exact diagnosis of so-called idiopathic or progressive pernicious anæmia. This disease, although first described by Addison has only during the last few years been generally recognised—about fifty cases having been recorded by various observers. So far as I can ascertain, Addison made no microscopic examination of the blood in this disease; but, in the Guy's Hospital Reports for 1855, Dr. Wilks, who had been testing the blood in reference to the number of white corpuscles, soon after Bennett's and Virchow's discovery of leukæmia, thus alludes to it: "In that class of cases which had specially gained the attention of Dr. Addison, and which he has designated, *idiopathic anæmia*, and where, above all others, it might be presumed that the existence of an excess of colourless globules was possible, no such condition has been found." This observation of Dr. Wilks has been confirmed by all subsequent writers on this disease; and, in addition to this means of diagnosis, other important microscopical changes have been noted in the blood in this disease, which help to differentiate it from chlorosis and other closely allied diseases, such as leukæmia, &c.

Observers have noticed, in blood drawn from persons with this disease by the prick of a needle, that the red corpuscles do not collect into rouleaux, as in health, but lie separately, or form masses of irregular shape; that these corpuscles are very noticeably reduced in number, are variable in size, of great diversity in form; some being oval, others spindle-shaped; some having a tail-like projection; some are larger than the white corpuscles, others not one-fourth of the normal size. In all the abnormal corpuscles, the so-called zoid or yellow substance (hæmoglobin) seems to be collected in one part, leaving the œcoid or rest of the corpuscle (stroma) clear and transparent, and this probably gives rise to the apparent nucleation of the corpuscles.

I have carefully examined the blood in one well-marked case of idiopathic anæmia, and I failed to find the small spherical red corpuscles regarded by Eichhorst as pathognomonic of this disease. Rosenstein, Grainger Stewart, and Bradford have also failed to find these "microcytes." These corpuscles cannot, therefore, be regarded as diagnostic of essential anæmia; but the three combined abnormal conditions—viz., diminution of the number of the red corpuscles, their paler colour, and the alteration of their shape and size—may be regarded as characteristic.

C. M. Sörensen, of Copenhagen, emphasises the counting of the red corpuscles for the purpose of exact diagnosis, and says that the number of red corpuscles counted (according to Malassez's method) is only one-fourth to one-twelfth of the normal number.

In August of last year I saw, in consultation with Dr. Ingle of this town, a case in which it was impossible to arrive at a correct diagnosis without a microscopic examination of the blood. The case was that of a married woman, who, during the whole of her pregnancy and for some time previously, had suffered from anæmia. Her condition during labour was so critical that Dr. Ingle asked a fellow-practitioner to be present at the delivery. She lost scarcely any blood during her confinement; but when I saw her, a few days subsequently, she appeared perfectly blanched, the lips and gums being quite bloodless. She had extreme breathlessness, palpitation, and giddiness. Loud venous and cardiac *bruits* were audible. The temperature was 101° Fahr., and the pulse was remarkably soft and compressible. I at first thought the case was one of idiopathic or progressive pernicious anæmia, which, according to Gusserow, Biermer, and others, occurs most frequently in pregnant women. A microscopical examination of the blood, however, showed a large excess of white blood corpuscles; the proportion of white to red being about fifty, instead of three, to a thousand. Now, as in progressive pernicious anæmia there is never any absolute increase of the white corpuscles, we were able in this case to give a more cheerful prognosis; the patient, under the influence of iron, digitalis, and good port wine, making a rapid and perfect

recovery. The woman suffered to an excessive degree from the temporary leukæmia or leucocytosis of pregnancy. Iron did good in this case; whereas it has been found useless in pernicious anæmia, arsenic being the only remedy which has hitherto been found beneficial. Whilst upon the subject of the microscopical examination of the blood, I must not fail to mention the ingenious hæmacytometer devised by Dr. Gowers for estimating the corpuscular richness of any specimen of blood. This instrument has the great advantage of accuracy and simplicity of application in clinical practice, and is an improvement in the latter respect upon the "compte globule" of Malassez, and the hæmatometer of MM. Hayem and Nachet. M. Malassez has also devised an instrument, the hæmacrometer, for estimating the amount of hæmoglobin in blood, which is both accurate scientifically, and most convenient clinically. He has pointed out that blood-corpuscle counting is of little diagnostic or clinical use unless combined with estimating at the same time the amount of hæmoglobin present.

To mention all that medicine has gained by the use of the microscope during the last few years would be to give a record of pathological progress during the period, and would include such large and important subjects as the recent pathology of tubercle, pyæmia, septicæmia, relapsing fever, blood-entozoa, the infective element of vaccine lymph, &c. One further application of it as an instrument of precision is of considerable interest at the present time, and ought, perhaps, to be noticed in this address. It was only in 1860 that Zenker of Dresden made out, post-mortem, the disease of trichinosis in a patient that was supposed to have had typhoid fever. How many cases of trichinosis had before that been attributed to some other condition, cannot be estimated. The microscope has discovered the disease, and by the aid of this instrument it will probably be stamped out. In the year 1876 there were in Prussia no fewer than twelve thousand inspectors charged with the duty of inspecting slaughtered swine.

Thermometer.—But the thermometer has done even more than the microscope to place medicine upon a scientific basis, and to refute the statement that "we have even yet no science of medicine." I think it may be said without exaggeration, that the treatise on "Medical Thermometry," by Professor Wunderlich has more than any other work furthered the progress of medicine during the last ten years; for it is only during this period that the thermometer has come into general use in the profession, although the first edition of Wunderlich's book was published at Leipsic in 1868. Probably no one phenomenon helps us so much as the temperature of a patient to reveal the existence of complications, and to predict the favourable or unfavourable issue of fevers and inflammations. Furthermore, as we have learned the natural course of most acute diseases, so have we come to trust less in drugs, and to leave more to nature, or perhaps I should say to careful nursing, rest, cleanliness, and suitable nourishment. Again, as the temperature can neither be feigned nor falsified, the thermometer may render us assistance in determining whether a disease is feigned or not.

Dr. Wilson Fox and others have shown that, by appropriate cooling of the body by baths and other external means, patients suffering from acute rheumatism, with a temperature of 110° Fahr., may be rescued from death. In the German hospitals the method of treating the pyrexical state by the external application of cold has come into general use, and has also to some extent been introduced into private practice. Jürgensen, Liebermeister and Hagenbach, Ziemssen and Immermann, Brand of Stettin, and others, have published statistics of several thousands of cases of fever treated in this way; from which it appears that the mortality has been reduced more than one-half, being now only from 3 to 10 per cent.

The value of the thermometer in clinical medicine has recently received a fresh illustration in the most interesting researches and Peter and Vidal on local temperatures in acute pleurisy, phthisis, and some abdominal diseases. M. Peter had for a long time been anxious to settle the question whether a local morbid action was accompanied by a local elevation of temperature, and he has been able to answer the question in the affirmative.

M. Peter has found in acute pleurisy, from a long series of investigations (1) that the parietal temperature outside the pleurisy is from one-half to two degrees Cent. higher than the average temperature of the patient; (2) that the more rapid the effusion, the quicker the elevation of temperature; (3) that when secretion is not going on, and the level of the fluid remains stationary, the elevation of the parietal temperature decreases, but the temperature is still from ½° to 1½° Cent. higher than the sound side; (4) that pleurisy not only raises the parietal temperature of the diseased side, but also that of the opposite side; but the parietal temperature of the diseased side is always higher than that of the healthy; (5) that, while spontaneous absorption of the effused fluid is going on, the parietal temperature drops gradually; (6) that in dry pleurises the local excess of heat is less than when there is effusion, and the return to the normal temperature also occurs more rapidly; and (7) that the absolute elevation of the local temperature on the diseased side is more considerable than the absolute elevation of the auxiliary temperature.

M. Peter has also investigated the results of thoracentesis upon the parietal temperature, and has found, when the effusion is not reproduced, that although there is, immediately after the puncture, a slight rise, which lasts for some hours, nevertheless the parietal temperature afterwards decreases, and continues to do so until the normal figure is reached, unless the effusion is reproduced, when the local temperature rises again.

The observations of M. Peter on local temperatures in pulmonary phthisis, which have been fully confirmed by M. Vidal, are even still more interesting. He believes that, as soon as tubercles occur at any point, the local temperature rises there; and he points out that in doubtful cases of phthisis, where the physical signs are not developed, this local thermometry may materially assist us in arriving at a correct diagnosis.

M. Peter has made a further communication to the Académie de Médicine on the subject of local temperatures in abdominal diseases; and he has indicated the differences between the local temperatures of the abdominal parietes in ascites, and in the various forms of peritonitis—viz., (1) that which arises by extension from a chronic phlegmasia of the stomach, "gastrite sclereuse;" (2) chronic tubercular peritonitis; and (3) chronic cancerous peritonitis.

M. Peter used an ordinary clinical thermometer for the observations, which, on account of its simplicity, he prefers to instruments of greater precision.

General thermometry has been found useful in diagnosing cerebral hæmorrhage from alcoholic poisoning, the general bodily temperature (rectal) falling at first below the normal in cerebral apoplexy, but not in drunkenness. Such a case is recorded by Mr. Foster in the *Lancet* for December 27th, 1879.

General thermometry also assists us in the differential diagnosis of true apoplexy from the so-called apoplectiform seizures, which occur in progressive general paralysis, disseminated sclerosis, cerebral softening, and also from uræmic coma. Charcot says, "I have demonstrated by repeated observations that, in true apoplexy, especially when it depends upon cerebral hæmorrhage, the temperature constantly diminishes some moments after the attack, and afterwards remains, generally for at least twenty-four hours, below the normal standard, even when intense and reiterated convulsive fits occur"; whereas, in the congestive attacks (so-called apoplectiform seizures) which occur in progressive general paralysis and in disseminated sclerosis, "the temperature, on the contrary, rises above the physiological standard and tends to become gradually more and more elevated, during the whole continuance of the attack."

In uræmic coma, according to Bourneville, the temperature of the body begins to fall at the onset of the seizure, and continues to sink as long as the coma persists, so that it may fall as low as 90 degs. Fahr. in fatal cases. On the other hand, in coma due to cerebral hæmorrhage or softening, the lowering of the temperature is slighter in amount, and, in cases not fatal within this period, rarely lasts longer than twelve to twenty-four hours" (Bastian).

The thermometer is also useful in forming a prognosis in these diseases, but into this I have not time to enter.

Ophthalmoscope.—Physics have also furnished us with the ophthalmoscope, an instrument which, besides being invaluable in the recognition of diseases of the eye has of late years assisted us materially in the diagnosis of intracranial tumour, syphilis, chronic Bright's disease, acute tuberculosis, tubercular meningitis, cerebral embolism, locomotor ataxy, and other diseases which need not here be specified.

In his address on "Ophthalmogy in its relation to General

Medicine," (delivered before the Medical Society of London) Dr. Hughlings-Jackson pointed out how frequently cases of supposed brain-disease are indirect effects of anomalies of refraction, readily recognisable by the ophthalmoscope, and how the correction of a hypermetropia or a myopia by appropriate spectacles may completely remove these quasi cerebral symptoms, and save patients from needless drugging with "nervine" and other medicines.

The following case, which came under my observation in January, 1879, is one of no uncommon occurrence. A lady who had been ill for some time, and under two medical men, had occasion to consult an oculist for some defect of vision. The ophthalmoscope revealed retinal hæmorrhage, such as is met with in some forms of chronic Bright's disease. The urine was now for the first time tested, and found to contain a considerable quantity of albumen; but, previously to seeing the oculist, renal mischief had never been dreamt of. The lady died about eighteen months afterwards, with well-marked uræmic symptoms.

Dr. Gowers relates a case, in which the detection of an embolus in the central artery of the retina was the first thing which drew attention to the existence of the cardiac affection from which the patient suffered. The patient applied to the Moorfields Ophthalmic Hospital for a defect of vision, and then she was found to have mitral constriction.

The ophthalmoscope often enables us to detect inherited syphilis, when other indications, such as the peculiar teeth, are absent. The relation of disseminated choroiditis to syphilis is extremely striking and important; and such a distinguished observer as Hutchinson has gone so far as to say, that the patches of disorganisation left by choroiditis are almost as pathognomonic of inherited syphilis as the notched teeth.

Other interesting recent researches in this field of medicine are those of Dr. Gowers on the diminution of the calibre of the retinal arteries in some cases of Bright's disease with increased arterial tension; and those of Quincke, Becker, and Dr. Stephen Mackenzie on spontaneous visible pulsation of the retinal vessels in connection with aortic regurgitation; and those of Mackenzie and others, of retinal hæmorrhage in connection with purpura, leucocythæmia, idiopathic anæmia, ague, and diabetes.

Retinal hæmorrhages have also been observed in septicæmia and pyæmia. In puerperal septicæmia, they almost invariably occur during the last two or three days of life, according to Litten; and they augur an unfavourable termination of the case. As these hæmorrhages are not found in acute specific diseases, such as enteric fever, they are useful in diagnosis as well as prognosis.

Another important condition, revealed to us by the ophthalmoscope, is the simple atrophy of the optic nerve—atrophy without preceding neuritis—which is seen in some cases of locomotor ataxy, and which may be of help in the recognition of this disease at an early stage. This simple optic atrophy can be sometimes seen before ataxy begins; and along with absence of the "tendon-reflex," or with the presence of the lightening-like pains, it is an almost certain indication that the disease has commenced.

The ophthalmoscope must, therefore, no longer be regarded as an instrument of use only to the ophthalmic surgeon, but as a most valuable instrument in the detection of many morbid states which come under the notice of the physician.

Laryngoscope.—Our knowledge of the uses of the laryngoscope in clinical medicine to-day is little in advance of what it was ten years ago.

Owing more especially to the careful observations of Dr. Marcet, we can detect tubercular disease in the larynx before there are any physical signs of its development in the lungs. When laryngeal phthisis is present, there is a "whitey, milky, probably purulent mucous fluid in the laryngeal cavity." The diagnosis of laryngeal phthisis is of more value in prognosis than is generally supposed; for if phthisis can be detected in the larynx, we may be quite sure that the lungs either are, or will shortly become, tuberculous, if not obviously so at the time. It is also a well established fact that those cases of phthisis in which the larynx is early involved are less amenable to treatment than most other cases; and hence we are compelled to give a more gloomy prognosis.

In inflammation of the larynx, the laryngoscope helps us to ascertain the presence or absence of membrane, which the report on the subject of croup and diphtheria presented to the Royal Medical and Chirurgical Society by a committee, of which Dr. Dickinson was chairman, has shown to be of the highest importance, both as regards prognosis and treatment. About 90 per cent. of the cases of membranous inflammation of the larynx prove fatal; and of the 10 per cent. of recoveries, there are few that survive unless tracheotomy be performed. Indeed, "if a child have laryngeal obstruction and membrane is seen in its throat, the chances are all that it will either die or be tracheotomised, and not improbably both." On the other hand, cases of non-membranous inflammation of the larynx, even those in which dyspnœa is severe and protracted, almost invariably end in recovery; and the worst cases hardly ever require tracheotomy. Membranous inflammation of the larynx is, in a vast majority of cases, diphtheritic, and accompanied by albuminuria; whereas, in non-membranous inflammation of this organ, the urine is seldom albuminous.

Sphygmograph.—In the field of medicine in which the sphygmograph has been used, the harvest has been more abundant than in the case of the laryngoscope, chiefly owing to the researches of Burdon Sanderson having been elaborated by Galabin, Mahomed, and others. The condition of high blood-pressure, is of the greatest importance clinically, and should be watched and estimated as carefully as the body-temperature, as there is no doubt it will be when the sphygmograph has been further simplified. High blood-pressure gives the earliest indication of the grave series of degenerative changes throughout the body known as chronic Bright's disease, and may, if neglected, lead to disastrous results both in disease of the arteries and of the heart. High blood-pressure is the cause of all so-called heart disease in old persons; it is very amenable to treatment, and its treatment is imperatively necessary. Dr. Galabin writes: "I believe that one of its (sphygmograph's) successful applications would be to estimate the probable duration of life, by showing how far the vascular system has undergone the changes to which it is subject with advancing years, or which may be the only indication of commencing Bright's disease."

Dr. Handfield Jones has recorded a series of cases in which, without albuminuria or other symptom of Bright's disease, the sphygmograph has sufficed to diagnose the disease, the high pressure in the pulse being really its pathognomonic symptom.

In a paper published in 1874, Dr. Mahomed tried to show that a chronic condition of high blood-pressure led to arterio-capillary fibrosis. This view he has further elaborated in a paper in the last volume of the Guy's Hospital Reports, where he says that the hard pulse—the pulse of high tension—is *the* sign of Bright's disease; and that it should altogether replace albuminuria, for this is only exceptionally present.

High blood-pressure gives rise to many functional as well as structural disorders. In the paper referred to, Dr. Mahomed described the occurrence of this condition in an acute and transient, as well as in a chronic and permanent form, as the result of certain blood-poisons, and as an *antecedent* of kidney disease. He has also demonstrated its existence in pregnancy, and thus indicated the connection between pregnancy and kidney disease (so-called), and thus with puerperal eclampsia.

This condition of high blood-pressure appears to be recognisable early in life, before it has given rise to any structural changes or symptoms, and may be described as depending on the *diathesis*, or less correctly on the *temperament*, of the person. It is a condition which, when once detected, should be closely watched and treated, otherwise it will develop into chronic Bright's disease.

Dr. Mahomed has elaborated the use of the sphygmograph in the diagnosis of aneurism of the aorta; he has shown that it may in some cases be of value in determining the site of an aneurism, and in estimating the amount of arterial tension present and the result of treatment upon it. The plan of treatment advocated in aneurism by Mr. Tufnell has for its object the reduction of arterial tension.

The sphygmograph is further valuable as a scientific means of watching the effects of drugs on the vascular system, especially with a view to their use in the treatment of Bright's disease and of aneurism by reduction of arterial tension. Above all, it is valuable as an educator and interpreter to the finger; it has taught us the meaning of the *tactus eruditus*, and will always be of the utmost importance in teaching students *what* to feel for in the pulse.

The possibility of recognising Bright's disease in its pre-albuminuric stage by means of the sphygmograph leads me to think, with Dr. Handfield Jones, that this instrument has a great future before it. When people become wise enough to

pay their doctors for keeping them in health by periodically examining them to see if there be any abnormal change taking place in their bodies, the sphygmograph must come into general use in our profession.

The remedies for high arterial tension generally are a reduction in the amount of nitrogenous food, purgatives, diaphoretics, bleeding, &c. A milk-diet is of the greatest value in some of these cases, as Dr. George Johnson was the first to point out. I have over and over again relieved this condition of the circulatory system by placing patients in bed and on a milk diet.

As the profession comes more and more to recognise the importance of increased blood-pressure, the practice of bleeding must come again more and more into fashion. The *pulsus magnus, durus et tardus*, which the old practitioners invariably bled, was exactly the pulse of high pressure as we now recognise it. (Mahomed.) There can be no doubt that in the present day we too much neglect venesection. In cases of apoplexy, with increased vascular tension, bleeding is beneficial; and also in uræmic convulsions, which Mahomed regards as probably due to minute cerebral hæmorrhages, produced by increased arterial tension, and not to the circulation of excess of urea or ammonium carbonate in the blood (Frerichs), or to anæmia of the brain caused by spasm of the cerebral arteries (Hughlings Jackson and George Johnson).

Some time ago, it was discovered that amyl-nitrate and nitro-glycerine have the property of relaxing the arterioles, and of thus temporarily reducing blood pressure. This discovery affords a most beautiful instance of what I do not hesitate to call scientific therapeutics, and affords another example that medicine is advancing to the dignity of a science. The drugs I have mentioned are especially suited to those cases in which the heart fails to overcome the great arterial pressure, as, *e.g.*, angina pectoris, and the angina attacks occurring towards the end of chronic Bright's disease. To Dr. Brunton we are indebted for the discovery of the action of amyl-nitrite in angina pectoris. In his Gulstonian Lectures, delivered before the College of Physicians in 1877, he says: "Some years ago I was placed in exceptionally favourable circumstances for studying the disease. I was able to watch a patient at every hour of the day and night, and to observe every phase of the attack. By the aid of Marey's sphygmograph, I discovered that, during the paroxysms, the blood pressure rose and the pulse became quick. As the pressure rose, severe pain came on in the heart, and when the pressure fell the pain disappeared. It was, therefore, natural to look upon the pressure as the cause of the pain, and my opinion was confirmed by the effects of bleeding; for this lowers the pressure, and each bleeding prevented an attack. The pathology of the disease thus seems clear; and the next question was, how to treat it? The remedy wanted was one to dilate the vessels, and this the researches of Richardson and Gamgee supplied. Nitrite of amyl they had shown to possess the very power which I desired; and thus their experiments on the pharmacology of the drug, and my observations on the pathology of the disease united, led to successful therapeutics. I administered the remedy, and the pain disappeared."

Nitro-glycerine has been shown by Dr. Murrell to have the same physiological action as amyl-nitrite, and may be used in the same cases.

One other point of great importance in reference to albuminuria and arterial tension which must not be altogether passed over, is the so-called "Albuminuria of Adolescents," which was the subject of a paper by Dr. Moxon in the Guy's Hospital Reports for 1878. In those cases of albuminuria which occur in young men from the age of sixteen to twenty-two, the albumen is not always present in the urine, but intermits; it is generally, however, present in the urine at some period of the day, most frequently in that passed after breakfast. These patients are usually languid, listless, complaining of headache, are anæmic, and "generally out of condition;" but after a variable time, under the influence of tonic treatment, the albuminuria usually entirely disappears, and the patient's health is restored. Now, in these cases of albuminuria the arterial pressure is quite normal, or low rather than high. I am disposed to agree with Sir William Gull, that the albuminuria in these cases is due to atony of vessels and nerves. He says, that albuminuria occurs in young and growing men and boys almost as frequently as spermatorrhœa.

The probable causes of such albuminuria are, in Dr. Johnson's opinion either (1) imperfect recovery from an acute renal attack; or (2) exposure to cold and wet, especially after being overheated and fatigued by prolonged or violent exercise (common in boys at school); or (3) imprudently prolonged cold bathing; or (4) excessive consumption of animal food and of alcoholic stimulants, either separately or combined; or (5) inveterate dyspepsia in persons of strictly temperate habits; or (6) mental anxiety; and in some cases a combination of two or more of the causes.

There can be no doubt that at the present time physicians do not regard simply the presence of albumen in the urine as so serious a sign as they would have done ten years ago. The late Dr. Murchison regarded some cases of albuminuria as due to hepatic derangement. In his work on "Diseases of the Liver," second edition, p. 573, he writes as follows: "There are also reasons for believing that albuminuria may be induced by hepatic derangement, independently of structural disease of the kidneys. It is now generally acknowledged that albuminuria, even when copious, and in the absence of any acute febrile disorder, does not necessarily indicate renal disease.

Aspirator.—Another instrument of precision for which we are indebted to physics is the aspirator, which has proved such a great boon to the physician and surgeon in the diagnosis and treatment of various diseases. I may, however, perhaps be pardoned for mentioning the great success which has attended our treatment of hydatid disease of the liver by this instrument. This disease is very prevalent in Cambridgeshire. During the eleven years I have been physician at Addenbroke's Hospital I have treated a considerable number of cases of this disease with the aspirator, and only one has proved unsuccessful, and this by reason of the aspirator never reaching the sac, which had thick cartilaginous walls, although three punctures were made. My experience does not coincide with that of my friend, Dr. John Harley, who advocates a permanent opening, and the withdrawal of the hydatids from the cysts, and even of the parent cyst itself. Before using the aspirator in cases of suspected pleuritic effusion, hepatic abscess, &c., I now almost invariably make a preliminary exploratory examination with a large hypodermic syringe, which is really a sort of miniature aspirator. I was glad to see the importance of this preliminary test recently brought more prominently before the profession in a paper by Dr. Greenfield.

Stethometer.—The stethometer invented by Dr. Ransome, of Bowden, is another instrument of precision, of value in the detection of some chest affections. Like the sphygmograph, the stethometer is not of ready application at the bedside, and has consequently not come into general use in the profession. It is capable, however, of rendering important information in some doubtful cases of lung disease.

Spectroscope.—Another instrument which promises to be of use in clinical and pathological investigations is the spectroscope, which has yielded some important results in the hands of Dr. MacMunn. By means of this instrument it is said we can distinguish blood from the bladder or urethra from blood from the kidney, and blood from the stomach from blood from the lungs, &c.

Electricity.—The application of electricity to the diagnosis and treatment of diseases of the nervous system has been placed upon a much more scientific basis during the last decade.

It is not contended for electricity that it alone is sufficient to enable us to diagnose any particular disease of the nervous system, but its reactions, when considered in conjunction with a careful consideration of a case in all its bearings, are often of valuable assistance in forming a correct view of it. Let me cite one or two examples in illustration of my meaning. A patient suffered, among other symptoms, from paralysis of the left leg. The reactions of the nerves and muscles to faradism and galvanism were normal. Now, in paralysis from brain disease, as a general rule, the electrical reactions of muscles and nerves are normal, which is not the case in paralysis from spinal disease, or from disease of the nerves and muscles themselves. The case was diagnosed as depending upon cerebral mischief, and in the necropsy a tumour was discovered in the right hemisphere, in the posterior parietal region. Again, a patient has right facial paralysis. The response of the nerve to electricity is considerably diminished. This shows that the paralysis has not a central origin, but is due to cold; that the case is one of so-called rheumatic paralysis.

Electricity also assists us in distinguishing functional from organic paralyses, and is valuable in the diagnosis of paralysis from lead-poisoning.

I have found electricity of considerable value in some cases

of progressive muscular atrophy and of infantile paralysis; and there can be no doubt of its use in removing chronic facial paralysis from cold, and, in some cases, of chronic neuralgia. Faradism and galvanism are the forms in which electricity is chiefly used in the present day; but statical electricity, produced by the old plate machine, has recently been found superior to these in certain cases of hysteria.

Metallo- and Magneto-Therapy.—Connected with the subject of electro-therapy are the very interesting investigations of Charcot and others, on the influence of metals and magnets on the human body in cases of hemi-anæsthesia. The subject is not altogether novel, as it was a belief, even amongst the ancients, that metals applied to the body exercised some influence upon the nervous system.

Metallo-therapy has, however, entered upon a new phase since, in 1848, Dr. Burq propounded the two following propositions: first, "That in certain states of the nervous system, plates of metal, placed upon the skin, have the power of altering general and special sensation and cutaneous vascular supply; and that the susceptibility of individuals to the metals generally used—gold, silver, iron, copper, zinc—varies; a patient sensitive to one metal being insensitive to another; second, that when it has been ascertained to what metal the individual is susceptible, that metal may be successfully administered internally to cure the morbid state of the nervous system."

In 1876, the Société de Biologie appointed a committee, consisting of MM. Charcot, Luys and Dumontpallier, to investigate the alleged phenomena, which presented its first report in April of the following year. The cases selected were chiefly those of hysterical hemi-anæsthesia, in which the patients had lost superficial and deep common sensibility, as tested by plunging long needles into the skin of parts usually most sensitive. The senses of taste and smell were usually abolished, and there was dimness of vision, with more or less colour-blindness. The skin was paler on the affected than on the sound side; the temperature also was lower, and the muscular power less. The results of the investigations bore out in every particular Dr. Burq's assertions. The application, for ten or fifteen minutes, of a metallic plate of gold, copper, or zinc—according to the susceptibility of a patient for a particular metal—to the anæsthetic part, restored for a time sensibility in the part. At first, a sensation of heat or numbness was felt in the part, which became red and of a higher temperature. A needle-puncture caused great pain, and made blood flow freely, though previously it was with the greatest difficulty that a drop of blood could be drawn from the limb, even when the needle was thrust through it. The muscular power in the limb was also increased; and taste, smell, and sight were restored. But these effects were not permanent; by the next day, the anæsthesia, &c., had returned. One of the most curious phenomena in connection with these experiments is what has been called the "transference" of sensibility—that is, a loss of sensibility on the sound side in the parts symmetrically opposite to those in which it has been restored.

In the two cases of hemi-anæsthesia, dependent upon organic brain disease, the metals restored sensibility to the part affected; and the effect, instead of being transitory, as in hysterical hemi-anæsthesia, was permanent.

The committee reported again, in 1878, on M. Burq's second proposition: "That the external metallic aptitude being known, the same metal administered internally will determine the same results as its external application." Five cases are recorded, in which hysterical patients, sensitive to either gold or copper, recovered sensation on the internal administration of the chloride of gold and sodium, or of the binoxide of copper. Very curiously, when the sensation had returned, the outward application of plates of gold or copper produced a relapse of the anæsthesia.

These experiments appear to have been conducted with every possible precaution against error or imposture; the phenomena not being produced when any other metal than the one to which the patient was susceptible was used. For instance, in a patient sensitive to copper, plates of platinum were substituted for copper without her knowledge, but no results followed; the copper being replaced, the usual phenomena ensued.

In case of hysterical colour-blindness (achromatopsy), by the application of gold to the temples, the colours were restored in definite physiological order; and on the occurrence of a relapse, they were lost in the same order—a circumstance which excludes all suspicion of fraud.

A satisfactory explanation of these phenomena has not yet been made. M. Burq attributed the effects of the metals to the production of superficial currents of electricity, which influence the nerves of the part; and M. Regnard has conducted some experiments which seemed to bear out this hypothesis. It has been shown, however, by Westphal and others, that sinapisms applied to the anæsthetic parts produce the same effects, even the "transference," as the application of metals; and hence Adler and others think that these agents act in virtue of their power of producing mechanical irritation. Others, as Dr. W. B. Carpenter, regard these effects as due "to a sustained attention on the part of the patients" (expectant attention); but MM. Charcot and Schiff seem to have eliminated, as carefully as possible, the influence of "expectant attention" in their experiments.

"Expectant attention" may explain much, but it does not explain all in these cases. "It cannot account," as the writer of the article on Metalloscopy, in the *Birmingham Medical Review* for April 1879, justly observes, "for a patient recovering her perception of colours in exact correspondence with physiological law, as related in the second report of M. Charcot's committee. It cannot account for transference—a fact discovered by accident, to the surprise of the observers, and, we are told in one case, the *horror* of the patient. It cannot account for the positive and constant results of certain agencies and the negative results of others; the different effects of the different metals; of the two poles of the magnet; of the magnet with the circuit open or closed. Such facts as the permanence of anæsthesia, caused by superimposing another metal; the prevention of anæsthesia by the same means; the prevention of anæsthesia by placing another metal on the central side of the first, and the absolute powerlessness of the same metal, when placed on the distal side, are also quite opposed to the same views."

The practical outcome of these investigations is, in the hysterical cases, at present not very great. The tendency to relapse and the production of "transfer" render the prognosis gloomy.

I ought not to conclude without uttering a word of caution, especially to the younger amongst us, not to rely too exclusively upon the information derived from the use of these instruments, to which perhaps there is a great tempation. The knowledge with which they supply us is, on account of its accuracy, of the greatest value, and at present the advance in the recognition and treatment of disease is chiefly due to them; but we must not ignore the aids which stood our predecessors in such good stead—the information with which the physiognomy, especially of patients, furnishes us—the estimation of the nervous element in patients, and the other features of disease recognisable by our senses, which I need not here mention, but which are known to every cultivated physician, and which cannot be measured by any instruments.

Original Communications.

ON FEVERS IN INDIA.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to Her Majesty the Queen.

(*Continued from page* 131.)

m. "As to the 175 cases on which Dr. Gordon based his conclusions, it was admitted that only seven were real cases of enteric fever, the others being so-called 'climatorial' fever." My exact words occur under paragraph 40, pages 69 and 70 of my first Report, and are as follow:—"Let the preceding records of individual cases speak for themselves. They include 175 of sorts, as already remarked, out of which number, if my views ar correct, only 7 *approximate to the standard* of typhoid fever according to British authors, while in not one instance has the disease been traced to pythogenic causes. If not traceable to specific causes, then it seems to me necessarily to follow that the disease has resulted from general influences, in other words, from endemic conditions affecting masses or individuals." Under paragraph 17, page 238, of my second Report, I reproduce the above remarks, and add: "The conclusion is that according to

the theory at present in vogue, a new name is given to an old disease—the *name* itself applied with reference to special, that is, pythogenic causation, which, as a matter of fact, cannot be traced, to the relative neglect of conditions endemic and climatorial which are ever existing and apparent, but the influence of which the present tendency is to insufficiently acknowledge." At page 25 of my second Report I express myself thus: "Who are right? The older medical officers who look upon enteric complication and typhoid condition, whether existing singly or combined, as being part and parcel of disease induced by endemic influences, or the younger, who, without being able to find conditions from which pythogenic influences arise, assign a specific term indicative of origin from such?" I submit that nothing whatever occurs in the critiques now being commented upon to lead to any other reply than that it is the former who are right, a reply which obtains confirmation by the *results* of the new theory expressed in section *e* of this communication, namely, that "of late years the proportionate fever mortality has increased nearly a fourth, and the proportion of fatal cases entered as enteric fever to all other fatal fevers has nearly quadrupled!

n. "Of what value, it was asked, could seven cases, scattered over thirteen years, and throughout a wide territory, be in determining a question of this kind?" I remark, of very great value, and in these respects, the circumstance indicates how extremely rare in the fevers of southern India and of Burmah are the phenomena which *approximate* to the standard of typhoid fever; also that, as stated in the preceding paragraph, they *not* being traceable to specific causes, "it seems to me necessarily to follow that the disease has resulted from general influences, in other words, from endemic conditions affecting masses or individuals."

o. It was "proposed to accept the diagnosis as given by the recorders, and he was not prepared to admit a greater margin of *error* in diagnosis than could have occurred if a similar number of medical practitioners had been applied to by circular in England." I have already stated the standard, which, in accordance with official instructions, I adopted, and with reference to which my inquiries were conducted; I have also referred to, and enumerated, the 104 different *standards* of what is, by different writers and reporters, held to constitute typhoid or enteric fever. With reference to these, the following remarks occur at page 232 of my second Report, namely, "the fact is now clear from the comments by medical officers," "that the standard thus laid down" by me in accordance with official instructions "is not that to which their remarks (by medical officers) in all cases referred; also that several standards have, in reality, been adopted, differing from each other as to the actual nature and phenomena of the disease, designated synonymously enteric or typhoid fever. This circumstance is, of itself, sufficient to account for whatever discrepancy exists in our respective views." In my two Reports much more on this part of our subject occurs; but I limit myself for the present to the following transcript from remarks by one of the oldest and most experienced medical officers with whom I had the honour of being associated. It occurs at page 95 of my second Report. "If Dr. Gordon determines with the definition laid down and quoted from Murchison that no fever is enteric except such as is caused by excremental poisoning (which is a question for further inquiry), then I consider *he was justified in rejecting the cases he did.*"

p. It is remarked that deducting twenty-five cases as furnishing no information either in one way or another with reference to the question of etiology, "it was found that by far the greater proportion of the remainder, according to the reporters, had occurred under fæcal effluvium from latrines, or the patients have been exposed to the *chances* of infection to local conditions which are known to be chiefly associated with enteric fever." In reference to this I remark that in my Reports I deal, not with *chances*, but with actualities; also, that as already more than once noticed in this communication, "in no one instance" among the cases recorded in those documents "has the disease been traced to pythogenic causes." Adverting to the remark just quoted as to the greater proportion of the remainder having occurred under fæcal effluvium from latrines, I add that cases so referred to are given at pages 52 to 60, and 140 to 147 of my first Report. At page 14 of my second Report I write, "I visited the station referred to, namely Cannanore," in February, 1879. On that occasion it was pointed out to me that "with reference to the troops among whom what was called 'enteric' fever occurred during the period from December 1872, till the end of April 1873;" of the barracks occupied by the infantry, the men quartered respectively in the barrack nearest to and farthest from the part of the cliff over which the filth had been thrown, suffered *equally* from fever, and to a much greater extent than those who occupied the intervening barracks completing the square, according to which form the barracks are arranged. I observed that the two first barracks are placed *end on* to the prevailing wind, whereas the two latter face *directly*, and thus receive complete perflation. At page 51 of my first Report I summarise the results furnished by two medical officers of high standing who were specially sent to investigate the outbreak, and with regard to those reports wrote that "from the report by Dr. Cornish, we learn that the cases of fever witnessed among the natives of Cannanore were the ordinary malarious fevers of intermittent type, common there and on the west coast generally during the land winds of the south-east monsoon." At page 25 of my second Report it is asked: "How, also, are we to account for the circumstance that at Cannanore, of the classes exposed to fæcal emanations, the older soldiers and the married families suffered either not at all, or very slightly, from a disease which prevailed to a great extent among the young soldiers? How are we to explain the fact that among the troops occupying Fort St. George, in the near vicinity of a large escape of sewage, and in the midst of what a *Society* journal calls one solidified stink, have had no *enteric* fever for years? In the latter instance young and newly arrived regiments did not garrison the fort."

g. With reference to the views expressed in my paper, namely, that "if in Britain such phenomena and pathological conditions" as are in this country held to constitute enteric or typhoid fever, "are due to the operation of filth causes in the system, and *to none* other, the evidence adduced is amply sufficient to justify the conclusion that precisely similar phenomena and pathological conditions occur in India as results of endemic and climatorial influences operating on particular states of the system in individuals; and that those influences are of themselves alone amply sufficient for their causation." The remark has been made that such views "reminded him of the state of medical opinion in this country twenty-five years ago, before the pathology of enteric fever, and the difference existing between that disease and other continued fevers, were understood." To these remarks it appears to me that replies have been already given in the preceding paragraphs of this communication. As already observed, my inquiries have reference to a particular *standard;* my conclusion was that in not one single case was that standard come up to among those investigated by me. I seek for an exact English standard, and find myself forced, with reference thereto, to write thus, namely, at page 14 of my second report: "In paragraph 40 (page 70) of my first Report I summarise the views of eminent authorities in Britain, France, and America with regard to the causation and phenomena of enteric fever; and as a conclusion arrived at, observe that such are the differences which exist in the writings of those authors, that we in India may fairly doubt whether their descriptions apply to similar conditions. According to the current medical literature of the day, difference of opinion increases with regard to the causation of enteric or typhoid fever throughout Europe generally, and in America." The *standard* according to which, officially, comments has been made on the Reports of my investigations, have on two occasions

been altered since my inquiries began. A reference also to what occurs in section *c* of this communication on the standard according to which some of the comments I am now endeavouring to meet have been made, will no doubt show that I was justified in making the following remarks which occur at page 241 of my recond Report, namely, "Naturally enough, if my investigations proceed from one defined starting point, and take thence a particular direction, the matter must be left very much as it was, in so far as views are concerned, having by turns different starting points and courses. This circumstance induces me to again indicate what I have several times already done, that with a view to facilitate further investigation with regard to *enteric* or *typhoid* fever in this part of India, it is very desirable that a definite standard be authoritatively laid down and stuck to as to what, having reference to causation and phenomena, shall be considered to constitute the diseases so-called. On the subject of fever in India allusion has already been made, namely, in section *d* of this paper, as to the chief difference between the more recent views as compared with the older, and the results which have occurred as a consequence of the application of the fever. Whether change of theory, with regard to disease in England, necessarily includes *advance* in knowledge, as regards disease in India, is a question beyond the actual scope of my present remarks; but as a conclusion to this paper I transcribe as follows the paragraph at page 246 of my second Report, with which the postscript to that document concludes, namely, "On these points, I remark, as already observed, specific causes of a specific disease being absent, the specific disease depending upon them cannot exist. If the cardinal signs of a particular disease are absent while those of another are present, the grounds are not clear upon which a name is applied to the existing disease in accordance with those that are absent, instead of with such as are present and obvious." On the subject of post-mortem appearances in so-called "enteric" fever, I will again refer to the summaries from authors of repute, given at pages 9 and 11 of my first Report, and to the following comments thereon in the latter, namely, "In these remarks, then, we find one set of authors definitely asserting that certain morbid appearances are invariably present in, and distinctive of 'enteric' fever, other writers stating that similar appearances not only occur in diseases other than in enteric fever, but as results of poisons, mineral and vegetable; while the fact is rendered apparent that similar lesions have frequently been observed in fatal cases of Indian climatorial fevers of non-specific character. Thus, causation, symptoms, and pathological characters of climatic fever being all present, surely the proper designation of the existing disease is sufficiently indicated thereby. Thus was the form of endemic disease of late years designated *enteric* or *typhoid* fever, recognised by the older medical officers and treated accordingly, with the relative success already shown, namely, that as compared with former times, of late years the proportionate fever mortality has increased nearly a fourth, and the proportion of fatal cases entered as *enteric* fevers to all other fatal fevers has quadrupled. If such really be the *results* of new theories of causation of Indian fevers, and of so-called improved diagnosis of them, I would, in the interest of the soldier, submit whether or not it is desirable on such terms to persist in that theory, and that *improvement* in diagnosis. For my own part I most earnestly say—No. It is not."

TWO CASES OF LUPUS TREATED SUCCESSFULLY BY THE EXTERNAL APPLICATION OF CARBOLIC ACID.

By J. C. HALL, M.B., Monaghan.

HAVING seen carbolic acid spoken of rather favourably as an external application in the treatment of lupus, by Dr. L. Neumann, of Vienna, I determined to try its efficacy in that disease, and had an opportunity of doing so in two cases with the following results:—

My first patient, E. T., æt. 16 years, an unhealthy anæmic girl, with a family history of phthisis (though none of her immediate relatives died of that disease), was admitted into Monaghan Union Workhouse Hospital on 4th March, 1880. She had suffered from lupus of the nose for 2½ years which caused partial destruction of the right ala. There were also patches of lupoid ulceration on septum and floor of nasal cavity, gum of upper jaw on right side, and left tonsil. I put her on cod-liver oil, syrup of the iodide of iron, and painted the ulcerated parts with pure carbolic acid twice a week. After a few applications the diseased parts of nose began to look better, but the gum and tonsil were very obstinate. However, at the end of two months they yielded to the treatment, and she was discharged cured on May 11th, 1880.

My second patient, Mrs. D., æt. 45, was admitted to hospital on 5th May, 1880. She is mother of three children, all of whom are healthy. Her mother died of phthisis, but she herself has always enjoyed good health. The lupus began in her case three years ago on the tip of her nose. By degrees it spread to both alæ and septum, and involved the entire muco-cutaneous surface of nostrils, which, when I saw her, was covered with thick hard scabs; the external surface of nose, extending as high as the bridge and to the cheek on either side, was of a dark red colour, with here and there patches of a darker red about the size of a small pea, and a few small round ulcerated patches. The entire red portion was covered with dry bran-like scales. The disease in her case was the form known as lupus erythematodes, and caused little or no loss of tissue, although of three years' duration. I gave her 4 m. doses of liq. arsenicalis three times a day, and had nose poulticed until scabs came off, leaving an ulcerated surface behind, which I painted three times a week with pure carbolic acid and the red non-ulcerated portion twice a week. After a short time the ulcers began to heal, and the red non-ulcerated surface to assume a pale and healthy appearance. She was discharged cured on 30th May, 1880. I may mention here that the application of carbolic acid caused little or no pain after first minute. The rapidity of the cure in this case may have been accelerated by the arsenic; but the first case, never having had any, shows that the chief remedial agent was carbolic acid.

Clinical Records.

PUNCTURE OF BLADDER PER RECTUM FOR RETENTION OF URINE FROM AN OLD IMPASSABLE STRICTURE, WITH SUBSEQUENT CURE OF THE STRICTURE.

By JAMES GILLESPIE, L.R.C.S.I.,
Clones.

MAY 30TH, 1878.—This day at noon, Patrick Connolly, æt. 48, five feet ten inches in height, and evidently at one time a powerful man, called upon me in urgent distress from inability to pass urine—a condition from which he had suffered during the previous three days. His bladder was greatly distended, and reached almost to the umbilicus. All reasonable effort with various bougies, and gentlest manipulation, failing to afford relief, I ordered hyd. c creta, grs. xx, to be immediately taken, and a warm hip-bath used as soon as he could get home, and promised to puncture his bladder in the evening if he should have continued until then without improvement. Long before the time appointed his wife came for me and said that he was "suffering great agony." Upon consultation with Dr. Hoskins, of Clones, we each tried

catheterism again for a few minutes, but without any good result. The stricture being now manifestly impassable, and the patient's life in danger, we delayed the operation no longer Having placed him leaning upon his knees and elbows at the edge of the bed—an elbow *outside* each knee—so as to make his thighs support and steady the bladder, as well as keep up a certain degree of compensating pressure, I introduced my left forefinger oiled into the rectum, and felt for the notch in the prostate gland; this was found without difficulty, and fluctuation ascertained in the space beyond. Keeping the point of my finger in the median line, a little behind the posterior border of the middle lobe of the prostate, and in the place where I had obtained fluctuation, I now under its cover introduced a Cock's trocar, withdrawing its point a little within the canula in order to avoid injury to the neighbouring parts—and at the spot where my finger rested I forced the instrument firmly and quickly through the walls of the intestine, the intervening recto-vesical fascia of Tyrrell, and the parietes of bladder, until I found its point free within the cavity of this viscus. The withdrawal of the trocar was followed by a strong gush of urine through the canula; this for about the first second of time was tinged with blood, but the remainder came away of a natural colour, and completely filled a large bowl, which upon measurement was found to possess a capacity of 76 fluid ounces: a considerable quantity also spilled on the floor before the bowl could be rendered available—this it would not at all be unreasonable to estimate as ten fluid ounces, but taking it at only half that amount there was fully *half a gallon* of urine removed from the poor fellow's bladder. The canula securely attached to a bandage passed around the loins, was allowed to remain, and a draught of tincture of opium and peppermint water ordered.

Upon the 3rd June, the canula was taken away.

On the 4th the patient resumed his occupation of labourer: upon this day, too, the stimulus of pressure was commenced with bougies, and assiduously carried on with short intervals of remission.

On the 17th there was epididymitis on left side; this speedily yielded to ℥viij. of Smyly's emetico-carthartic mixture.

On the 24th July he could make water in a stream, and on the evening of August 24th, when he called upon me, I succeeded in passing a filiform whalebone bougie, after first reducing the thickness of its extremity one half: I could only leave it in for an hour and a half upon this occasion as he was obliged to go home.

Permanent dilatation was employed on the 25th Aug., and repeated frequently for periods varying from twelve to thirty-six hours until 1st November, when I passed a No. 12 gum elastic catheter, and tied it in. He was now ordered iodide of iron in pill, and forbidden to take alcohol in any form.

By 18th November, upon examination, he was found cured.

After puncture of this patient's bladder, bougies and catheters were used altogether with him upon sixty-two occasions, viz., thirty-four times before filiform bougie passed through, and twenty-eight times afterwards when permanent dilatation was practised. The stricture was of the long kind, very hard and stubborn, and appeared to occupy the entire of spongy portion of urethra from about two inches behind meatus. There was great suppuration within the urethra, a few slight rigors also, treated with some doses of quinine. The recto-vesical wound healed readily, and gave no trouble. The catheters and bougies were secured in bladder by a woollen thread tied around glans penis.

As the previous history of this patient in connection with his ultimate recovery is calculated to encourage remedial effort where even the faintest prospect of ultimate success exists, I will briefly give it in a condensed form:

He had served for twenty-two years as a soldier in India, first in horse artillery in East Indian Company's service for twelve years—then at amalgamation of East India Company with Imperial troops he joined 3rd Dragoons, in which he served for ten years. Was through the Mutiny in India under young Havelock; served through Abyssinian Campaign; was in China in 1854 at the taking of Canton. During all his service he had retention of urine only twice, first, shortly after he joined the army in India, and secondly in China in 1854—*from this latter period he observed the stream gradually becoming smaller;* he had never been intemperate.

About September, seven years before I saw him, he found himself unable to urinate except in drops, and applied immediately in succession to two medical gentlemen who tried catheterism, but without relieving him: during one of these operations he bled from the urethra "severely." Finding himself "in a bad way" he started by next train and obtained admission into a public institution, where catheterism being tried at once without success, after consultation, a cutting operation in the perinæum was performed at once, but without entering the urethra, as would appear from the fact that no urine escaped from the wound—only a little blood—and that a poultice was applied over it, and no instrument entered through it. At this time he could make water by drops, which relieved him, but he suffered great pain.

Here he remained for a month, by the end of which time he had become able by dint of baths, &c., to pass a stream of water "the thickness of a knitting needle," and to go home much improved. During this month, however, no attempt at getting through the stricture had been successful, but no doubt, had he remained for a longer time as requested, he would then have got cured.

In conclusion, I have only to add that Connolly has led an active and laborious life during the last eighteen months, out in all kinds of weather, and that I spoke to, and saw him yesterday (June 1, 1880), in the enjoyment of excellent health.

Translations.

DEAFNESS:
ITS DEGREES, CAUSES, AND THE VARIOUS MEANS RECENTLY DEVISED FOR DIMINISHING ITS INCONVENIENCES. (a)

By Dr. LADREIT DE LACHARRIERE.

Translated by W. DOUGLAS HEMMING, F.R.C.S.Ed., Bournemouth.

(*Continued from page* 133).

Affections of the Eustachian Tube.—The perviousness of the pharyngeal canal of the ear is as necessary to the perception of sounds as that of the external auditory meatus. As soon as the permeability of the Eustachian tubes is diminished, sensorial troubles begin to be produced; they are the result of modifications operating on the middle ear. The Eustachian tube equalises the pressure of the gas in the middle ear with that which the atmospheric column exercises from without on the surface of the membrane; when the Eustachian tube is obliterated or simply narrowed, the external pressure becomes greater than the other, and forces in the membrane, which little by little is pressed into the depths of the tympanum. The position of the ossicles is modified, and the transmission of the sound waves cannot take place under the ordinary conditions. The first symptom is buzzing (tinnitus); it is like the sound which one hears on placing a large shell to the ear. This vague and continuous sound occurring together with some degree of deafness, is characteristic of obliteration or narrowing of the Eustachian tube, or at least of obstruction to the circulation of the sound waves by the natural channel. Sounds which we utter are transmitted directly to the ear by the Eustachian tubes, and when these are altered in calibre, the affected persons do not hear their own voices distinctly. All affec-

(a) "Annales des Maladies de l'Oreille, du Larynx," &c. 1880.

tions of the tubes cause their obliteration or narrowing by the swelling of the soft parts. They have sometimes a very strong analogy to those of the external auditory meatus. We may mention simple obstruction by inspissated mucus, catarrhal affections, inflammatory diseases, herpetic manifestations in the pharynx, syphilis showing itself on the vault of the pharynx by mucous patches, naso-pharyngeal polypi, which may originate both in the neighbourhood or even in the very opening of the tube. Lastly, tumours which compress the orifices or set up in their vicinity a cause of irritation, frequently cause alterations in the tubes and auditory trouble.

Diseases of the Tympanic Cavity.—Acute affections of this region, when they are somewhat severe, cause almost complete cophosis; but the perception of sounds through the cranial bones remains. We have, without subjective phenomena, proof that the cause of the deafness is exclusively in the middle ear. Diseases of the middle ear may affect the mucous membrane of the tympanum, the membrana tympani, or the chain of ossicles. Catarrhal affections cause abundant secretion, which, not finding exit by the Eustachian tube, fills the tympanum. If the inflammation is somewhat acute, perforation and partial or general destruction of the membrane is produced. Moorhead, however (*Brit. Med. Journ.*, Aug. 31, 1878), has published a case of abscess of the tympanum opening into the Eustachian tube. In all these cases the changes in the tympanum are sufficient to cause some degree of deafness.

As a consequence of chronic inflammatory affections of the tympanum we have observed thickening and sclerosis of the membrana tympani. When the membrane is simply thickened it has a greyish, slate-coloured appearance, the colour of grey paper. Towards the centre we recognise the traces of its union with the handle of the malleus by a whitish, fibrous tract indicating an exaggerated fibrous engorgement at this point. There is no light triangle, the curvature of the membrane not allowing the refraction of the luminous rays.

Thickening of the membrane is very often accompanied by depression of it into the tympanum either by adhesions or from contraction of the intrinsic muscles of the ear. Such lesions would seem incompatible with even passable hearing. It is nothing of the sort, however, as I often see patients the aspect of whose ears would lead one to think that deafness was far advanced, who yet hear very passably, and would not seek any advice for their ears if they were not tormented by tinnitus, which wearies their existence. This tinnitus is characterised by a rustling, which the patients compare to the noise of leaves agitated by the wind, or to a very soft hissing. These two sounds are caused by a certain degree of compression of the fenestræ, and consequently of the labyrinthine fluid. The degree of deafness is in general much more marked in simple thickening of the membrane when the handle of the malleus is much displaced, since the chain of ossicles is then itself affected.

Sclerosis of the membrane occurs more slowly than simple thickening. It is characterised by cellulo-fatty deposits in the thickness of the membrane, either beneath the external or the internal mucous layer. The membrane assumes an irregular, greyish white, flocculent appearance. Generally this morbid condition of the ear is accompanied by marked cophosis. During the period of transformation patients complain of auricular noises, then all is quiet, but deafness daily increases, if treatment does not intervene to arrest the progress of the disease and restore to the membrane some of its lost mobility.

Calcareous Patches.—We observe also in the thickness of the membrane deposits of another kind, to which we give the name of calcareous patches. They consist of material deposited in the interstices of the membrane; sometimes they invade a considerable portion of the membrane and are semilunar in shape, occupying the circumference; at other times they are disposed in patches of irregular shape; sometimes they are single, at other times there are two, or even three. They are placed on either side of the handle of the malleus, and in the most sloping parts. In the unaffected parts the membrane sometimes preserves its physiological appearance; at other times it has a neutral tint which shows a morbid process; the handle of the malleus is very projecting.

The deposits consist of a chalky material, which is carbonate of lime. They may appear at all times of life; but according to Toynbee they coincide with similar deposits in the tympanum, around the chain of ossicles and the fenestra rotunda.

We do not know the conditions under which these calcareous products are formed. Miot attributes them to suppuration of the middle ear; but how is to be explained the presence of these patches on membranes which in their vicinity preserve an aspect of integrity and without rupture? We cannot admit this explanation.

No more do we believe that calcareous patches are much more frequent in the gouty; they are not changes which we consider as habitual manifestations of that diathesis. Politzer, who has well described calcareous deposits of the membrane, has observed them at all ages, and has ascertained that they are not incompatible with good hearing. It is possible that a calcareous patch deposited in the middle of a healthy membrane would not cause much auditory trouble; it would not necessarily be the same if the deposits covered a large surface or were very numerous. In this case the deafness is very marked, and is considerable when the patches are in the interior of the tympanum and the fenestræ.

Osseous Changes in the Membrane.—In my opinion this degeneration is rare. Triquet, however, affirms that it is a frequent complication in the otitis of gouty patients. This cartilaginous or osseous transformation may be partial; according to this author the membrane may acquire a strong hardness without the deafness being greater than in others in whom the septum only appeared cartilaginous. Bonnafont observed it twice. Delean cites the case of a congenital deaf mute aged twenty-three whose membrane was ossified, as well as a woman aged forty-five who became deaf from the same cause.

Relaxation of the Membrana Tympani.—The membrana tympani may, as the result of many diseased conditions of the middle ear, undergo a sort of relaxation, lose its natural contraction, and approach nearer to the promontory than in the normal state. Toynbee attributes this state to hypertrophy of the mucous layer and inflammation of the fibrous layers.

Kramer denies its existence. I think, however, we must attribute to this condition the care some people have to *wake*, as they call it, their ears by forcing air into the tympanum. This precaution causes improvement for a few moments.

Wounds of the Membrane.—Wounds of the membrane give rise to only transitory deafness when the membrane alone is injured, but not so when the organs of the tympanum are affected. The proof of this is found in the harmlessness of surgical paracentesis of the membrane, which indeed possesses a degree of cicatricial activity unsurpassed by any other part.

True Inflammation of the Membrane.—The membrana tympani may be the seat of small abscesses which are developed in its thickness. It may be the seat of variolous pustule, or of herpetic vesicles which by inflaming the neighbouring cellular tissue, may cause lasting perforations.

The degree of deafness which results is not in relation to the extent of the perforation. We have observed that a small perforation may give rise to more marked deafness than a much greater loss of substance.

In both cases the impairment of hearing is considerable; but we can understand that, when the membrane presents a small opening with more or less thickened borders, which does not allow free passage of the sound waves, the conditions are so modified that the physiological transmission by the chain of ossicles cannot take place with the ordinary precision.

On the other hand, when the perforation is large, and when the loss of substance has involved that of the chain of ossicles, the sound waves, no longer finding any obstacle, can act freely on the fenestræ. It is true that their energy, instead of being concentrated on these organs, as the crystalline concentrates the rays of light, is partly lost, so that deafness is always marked, though not complete. Itard admits that an opening in the membrana tympani may be sometimes a congenital lesion. We have, he says, among our congenital deaf mutes, a child who has one membrane perforated, and the other completely destroyed, without, her parents avow, her having had discharge at any time since her birth. He also reports that a child was brought to him who had vomited milk through the ears; there was no membrane in either. Without denying these facts, which we have not ourselves observed, we think they must be very rare, and remembering the little care and attention

which is given to discharges from the ear in all young children, we must admit that the evidence of the parents is not of much value, and that affections of the ear may have been forgotten or unperceived.

Authors are not agreed as to the results to the hearing of perforation of the membrane. Formerly it was admitted that destruction of the membrane involved necessarily total loss of hearing; experience now contradicts this opinion, and I have known many persons who for twenty years have had perforations of the membrane, without their deafness making much progress.

Catarrhal affections of the tympanum are very common. Sometimes they are caused by inflammation of the naso-pharyngeal mucous membrane, which reaches that of the tympanum through the Eustachian tubes; sometimes, on the other hand, they are primary. The objective symptoms of catarrh of the middle ear are—a red congestive suffusion which may be seen through the membrane, the slightly neutral tint of which does not reflect the light to the same extent. If the catarrhal affection be of long standing, and if the Eustachian tube is obstructed by the swelling of the mucous membrane, this neutral aspect is more and more marked; the membrane becomes of a greyish tint from the presence of mucus accumulated in the tympanic cavity. During the period of regression the membrane resumes an appearance which approaches more and more the normal state; but in general there remains about the handle of the malleus a red fibro-vascular engorgement, which may be cured and disappear, but which may also become organised and keep the chain of bones in a state of rigidity incompatible with perfect hearing. From the commencement of these troubles people experience acute lancinating pain, most intense in the ear, and radiating over the whole side of the head. Little by little the acute pain diminishes, leaving behind a sort of numbness. Patients complain that their voice resounds disagreeably; they have tinnitus, characterised by the vague shell-like sound mentioned when speaking of changes in the Eustachian tubes, and by roarings and rustlings caused by compression exercised on the labyrinthine fenestræ; lastly, they may experience vascular beatings perfectly synchronous with the pulse, of the arterial nature of which there can be no doubt. Lastly, there are buzzings which disappear. Patients are at first completely deaf, but the transmission of sounds by the cranial bones is generally preserved, and shows that the obstacle is exclusively in the tympanic cavity.

Inflammation of the tympanic mucous membrane may become very intense, and is then an acute otitis. The mucous membrane secretes abundant muco-pus, which may discharge itself by the Eustachian tube, but as this is generally obstructed by the inflammation, the fluid finding no issue, perforates the membrane. In acute otitis the pain is sometimes intolerable. Patients are unable to swallow, and the least pressure on the ear is very painful. They get no sleep or food, and only experience relief when an opening in the membrane, artificial or spontaneous, lessens the tension of the parts by permitting the outflow of the muco-pus. The symptoms are the same as in simple catarrh, only much more intense. It is not uncommon to see a general inflammatory condition produced characterised by fever and a catarrhal condition of the digestive tract. It is unnecessary to add that in the acute stage, and until the fluid has escaped, hearing is entirely abolished. If the inflammation reaches the periosteum, and even the osseous surface, the characters of the disease are modified, and otorrhœa is produced. This affection, characterised by muco-purulent secretion from the tympanum, is accompanied by ulcerations of the mucous membrane of the tympanum, and a swelling of the soft parts, which as a first result closes the Eustachian tube and inevitably causes rupture of the membrane. Sometimes this rupture is linear in form, sometimes it causes more or less considerable loss of substance, which leaves behind it an irreparable lesion. In any case, otorrhœa is accompanied by considerable deafness. It is almost complete at first; when the fluid flows freely it diminishes, but remains marked, unless the disease is of short duration, which is very rare; and in this case, if the membrane presents simply a slit, it may recover almost its normal condition; but more frequently the inflammation of the tympanum causes thickening of the tissues and lasting lesions which involve deafness.

The Mineral Waters of Europe.

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS, FOR THE GUIDANCE OF THE PROFESSION AND THE PUBLIC.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,
President of the Pharmaceutical Society of Ireland, &c.

WITH NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,
Lecturer on Materia Medica and Therapeutics at the London Hospital.

(*Continued from page* 135.)

COMING, then, to the effects of the individual classes, we may briefly sum up their commonly reputed remedial value prior to a fresh investigation of their merits.

1. *Salines.*—The so-called bitter or purging waters owe their aperient qualities to sulphate of magnesia and soda, the effects of which as medicines need not be described. In small repeated doses they can be made to induce an artificial diarrhœa; in large ones they are more or less cathartic. The more freely diluted the more active they usually are, and in this class of waters, therefore, we have highly diluted saline laxatives, modified in their action by the other ingredients and the temperature at which they are taken. These waters are highly prized as occasional or habitual aperients, and are regarded as specially useful in congestion of the portal system, and in the condition termed plethora. Püllna water is rich in both sulphates; Friedrichshall contains less, but has in addition a good deal of sodium chloride. Cheltenham is much weaker. We have also saline waters in which magnesium sulphate is absent, or nearly so, as in Leamington. In some of these we find carbonate of soda present, as in the highly prized waters of Carlsbad. Next come waters in which sodium chloride is the sole or chief ingredient. Some of the most celebrated springs, as Kreutzmach, Wiesbaden, Baden, Homburg, belong to this division. The action of these waters is solvent and alterative. The salt in the blood is temporarily increased; it rapidly passes into the several secretions. Tissue metamorphosis is increased, the bowels rendered more active, and the kidneys notably stimulated. Absorption is thus promoted, but the belief in disappearance of tumours under its influence is mostly confined to the neighbourhood of the Spas, where these wonders are related. In gout some of these salt waters are very useful. In anæmia, hepatic disorders, and uterine maladies they are also in repute. In scrofula and chronic rheumatism those springs which also contain iodides and bromides are indicated.

2. *Alkaline Waters.*—In this class we have the direct and the remote alkaline effect to consider. Their antacid value as soon as they enter the stomach will be in proportion to the alkali contained. In Vichy, the type of these waters, we possess a powerful remedy containing a considerable quantity of sodium carbonate. As soon as

it is absorbed it will increase the alkalinity of the blood, and its effect is soon seen in diminishing the acidity of the urine, which fluid it may neutralise, and even render alkaline, if unduly pushed. This class of waters may therefore be employed in acidity of the primæ viæ, in chronic cutaneous affections, in some bronchial and pulmonary diseases, in calculi, diabetes, Bright's disease, gout and rheumatism, glandular enlargements, and functional uterine disorders. The indications are indeed too various to be discussed in a paragraph. Besides Vichy, already mentioned, Bilin and Vals are powerfully alkaline. Ems and Royat are much weaker. Mont Dore and Wildungen contain comparatively little soda, but the former boasts its small quantity of arsenic ; the latter its iron.

3. *Chalybeate Waters.*—The medical use of iron is so everyday an occurrence that no wonder waters known to contain the metal should be popular. There is little doubt that iron may be assimilated, if taken in these waters, in cases in which it is scarcely tolerated in the most refined pharmaceutical productions. When it occurs as carbonate it is most palatable, and often most effectual. Iron is often present in other classes of water affording useful combinations. Spa is the most popular spring of the kind, and very accessible. Schwalbach contains much gas, and is therefore good for bottling. Tunbridge has but little gas, but deserves its popularity as a simple chalybeate.

4. *Sulphurated Water.*—From what has been stated in the chemical division of this report, readers will be prepared to doubt whether the repute of these waters ought to be attributed so much to their sulphur compounds, and from the remarks made on waters in general, the other influences may obtain more notice than usual. Many of the most famous sulphurated waters are little else than indifferent ones with a flavour of sulphuretted hydrogen. Eaux-Bonnes and other Pyrenean springs, as well as Aix-les-Bains, may be thus described. It may be stated, however, that lately some writers have assigned remarkable therapeutic properties to sulphides in minute doses. Such statements must be received with caution, and certainly are incapable of accounting for the clinical records of the chief sulphurous spas. Some of these are in repute for respiratory diseases, as Eaux-Bonnes. In digestive disorders Eaux Chaudes is regarded as more suitable, while Luchon is celebrated for skin affections ; and at Aix-la-Chapelle the claim is asserted for removal of poisons from the system, whether syphilitic or metallic. No doubt all these waters stimulate the kidneys and skin. They are usually supposed to quicken the circulation, though some attribute to them an opposite effect. Whether in the diuresis induced the quantity of urea excreted is increased, is still in question. The bowels act more freely under their use, the dejections sometimes becoming blackened. Enlarged glands are reduced. Anæmia may follow prolonged use. These waters are most used in chronic rheumatism, in scrofula, in diseases of joints, and in numerous skin diseases. They are employed in some chronic respiratory diseases, in functional uterine disorders, and to eliminate mercury, syphilis, &c., from the system. Some of the most popular springs have been named ; to these should be added Harrogate, which, although English, is one of the most powerful, and situated in a fine bracing country, to which a visit might often be more restorative than a Continental trip, if less fashionable.

Indifferent Waters.—Under this head are grouped waters containing a minimum of solids ; some of them much less than ordinary potable water. As certain qualities are claimed for them it would be better to call them *table* waters, for this is their chief use in bottle, though many are largely used at their springs for bathing, especially the thermal ones. In the bottled waters the presence of carbonic acid would seem to be the chief point, for this gas renders them palatable, and we have seen that it may stimulate digestion. The marvellous qualities attributed to some of the ingredients met with in minute quantities—mere traces—serve to amuse the credulous ; and sometimes the presence of these substances induces people to replace injurious fluids by these innocent waters. Those waters which contain a little lime and magnesia are sometimes distinguished as earthy waters. Some are more related to saline, as they have enough sodium, carbonate and chloride, to give them character. Others contain traces of iron, lithium, or other minerals. It is, however, chiefly as pure water, usually agreeably aërated, that we must regard them ; and the effects of drinking water and of carbonated water have already been considered. Buxton and Bath represent these waters in our own country. The water of the latter has lately been successfully aërated. Malvern, and numerous "holy wells" that have lost their popularity, also furnish excellent table waters. France sends us the favourite St. Galmier, and Germany numerous specimens.

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Wolverhampton 16, Bristol 17, Portsmouth 17, Edinburgh 20, Glasgow 20, Bradford 23, Hull 23, Newcastle-upon-Tyne 23, London 24, Sheffield 24, Brighton 24, Nottingham 26, Norwich 26, Birmingham 26, Manchester 26, Plymouth 26, Oldham 27, Sunderland 28, Liverpool 28, Leeds 29, Leicester 33, Dublin 35, and the highest rate 38 in Salford.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 19, Bombay 27, Madras 32 ; Paris 28 ; Geneva 20 ; Amsterdam 20, Rotterdam 26, The Hague 27 ; Copenhagen 20 ; Stockholm 33 ; Christiania 28 ; St. Petersburgh 42 ; Berlin 44, Hamburg 22, Dresden 29, Munich 34 ; Vienna 23, Buda-Pesth 42 ; Rome 27, Turin 38 ; Alexandria 48 ; New York 38, Brooklyn 30, Philadelphia 24, and Baltimore 21 per 1,000 of the population.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, AUGUST 25, 1880.

THE PROSPECTS OF MEDICAL REFORM.

THE observations make by Earl Spencer and Mr. Mundella, the Lord President and Secretary of the Privy Council, to the deputation of the British Medical Association the week before last ought to be accepted at once by medical reformers as a warning that redoubled energy will be necessary during the Parliamentary recess and at the opening of the next session, lest the obstruction of the General Medical Council and the open opposition of the Scotch Corporations may succeed in defeating the effort at medico-educational amendment which the profession has been making. It must be perfectly clear to every one who has studied the ministerial pronouncement to this deputation that the Government is indisposed to "take the bull by the horns" and trample down the obstruction of vested interests, and that this indisposition to deal with the question of medical reform arises not from any general unwillingness to grapple with abuses, but from a feeling that the medical profession are not worth fighting over. This impression is the reasonable result of the medico-political occurrences of the last twelve months, and we do not blame either the Lord President or Mr. Mundella for a disposition to act according to their present lights. The Duke of Richmond and Lord George Hamilton, the Lord President and Secretary of the Council in the last Government, had been compelled to grant a select committee upon the medical bills by the efforts of the Scotch members who—acting on behalf of the Scotch licensing bodies—were "canny" enough to see clearly that the delay which such an inquiry would involve, was a half victory for their obstruction policy. They would not have succeeded in getting this select committee if the profession had been true to its programme, and had vehemently represented what was, and is still, perfectly true—that as regards conjoint examination and direct representation—the salient points of the bills, no serious difference of opinion existed in the profession, and no inquiry was needed. But the profession did not put out its strength to support the then Government against the appointment of this committee as it ought to have done, and accordingly Lord George Hamilton was obliged to shelve the bills and to retreat before the Scotch bodies. At that time we expressed our sincere regret that the medical reformers had allowed themselves to be hoodwinked by this plausible demand for inquiry—meaning thereby a postponement which the Scotch bodies hoped—might end in indefinite adjournment. But what followed has put medical reform in a much worse position than the mere delay could cause it to occupy. The Select Committee met and took the evidence of fourteen witnesses, and then suspended the hearing of the cause. Of these fourteen witnesses eleven were either members of the Medical Council or Scotch obstructionists, two were medical reformers, and one was a nondescript who was asked a few questions because he happened to be in London. Thus, the testimony delivered before the committee was an almost unbroken laudation of the *status quo*—a chorus in honour of the General Medical Council, and a reiteration of the protestation that the nineteen-portal licensing system is everything that is to be desired. and that neither that system nor its patron — the Medical Council—ought to be interfered with on any account. Is there, then, anything surprising in the fact that the partial hearing of evidence by this committee, combined with the assiduous earwigging of the Government by the members of the Medical Council who have access to them, has left upon the minds of Lord Spencer and Mr. Mundella an impression that the doctors had better be left as they are for the present. When the new Parliament assembled in the early part of last May, and when the question arose as to the propriety of re-appointing the Select Committee and completing the evidence, we then urged, with all emphasis, that the Government should be stimulated at once and with energy to re-appoint. Our hope was that the case for the defence of the Medical Council and the gross abuses over which it has reigned, having been closed before the committee, the case for the profession at large as plaintiff might have been readily heard within a fortnight, and a report agreed to by the committee upon which final medical legislation might be based next February. Unhappily our advice was not followed, for the Reform Committee of the British Medical Association was totally disorganised by the loss of Mr. Mills's seat, and the Medical Alliance Association had not time to organise a deputation before

the ministerial mind was made up. Therefore, the Government, glad to escape for the fraction of a session which was before them from the necessity of burthening themselves with work which was not pressing, refused to re-appoint the committee. It would seem from the remarks of Lord Spencer and Mr. Mundella that the committee may never be re-appointed, and, therefore, that the case for medical reform will never be fully heard, and towards that consummation we observe that Mr. Horatio Nelson Hardy lent his voice. We are at a loss to understand in what capacity or by what authority (save his own) this gentleman undertook to advise Lord Spencer to dispense with the testimony of medical reformers, nor can we comprehend the nature of the mental process by which he justifies himself—the President of the Medical Alliance Association—in attending as spokesman on behalf of a Bill which that Association repudiates, and in advising that that Association and other witnesses for medical reform be not heard.

We have now before us a very serious, but not in any respect a desperate condition of the prospects of medical reform. We have, moreover, the significant statement of Professor Haughton at Cambridge, that the Government contemplates creating a state examination superior to and destructive of the examinations of all licensing bodies. We do not know upon what authority the statement has been made, but *primâ facie* it would seem not at all an impossible solution of a dispute respecting which the selfishness of corporations and the conservatism of the General Medical Council have made compromise almost impossible. The Government has no doubt learned what the profession knew three years ago, that the Scotch licensing bodies must be reformed by force or not at all, and that coercion is the only method possible with them. It is natural that the Government should shrink from petty legislation which involves the necessity for coercion, but if it must accept that necessity it would seem not unlikely that the Government will overcome the whole difficulty by a trenchant measure applicable to all licensing bodies. It is not the first time that a state examination has been spoken of. Some years ago the late Sir John Gray elaborated such a scheme and submitted it to Parliament, but it was, of course, futile for any private member to encounter the aggregate opposition of the nineteen licensing bodies, and the question now before us is not whether the present Government will be strong enough to override that opposition, but rather whether it cares enough for medical legislation or supposes that the country will care enough about the matter to justify the making of medical reform a matter of ministerial policy.

We are now on the eve of the Parliamentary recess, during which truce from political warfare the Government has promised to consider the question, and the medical reformers have before them seven months wherein to regain the ground which has undoubtedly been lost to them. Our earnest advice to them is to attack the Government with all the force at their command, to obtain from the profession at large such a demand for reform that no doubt can remain on Mr. Mundella's mind that there is unanimity and firmness of determination to secure a thorough amendment of the present medico-educational system, and to agree, if possible, upon a Reform Bill which will represent the hopes of the entire profession, and which will be accepted as a good compromise of contending views. There is not the least reason why such a demand should not be submitted to Government as will at once decide them to undertake medical legislation next session. The profession is united upon the point, and before its united voice the obstruction of the General Medical Council and the pocket interests of the Scotch colleges could not stand for a moment, if only a decisive declaration of opinion be organised and the political influence of such declaration fully utilised.

GOVERNMENT RESPONSIBILITIES FOR IRISH SANITATION.

THE profession in Ireland, not less than the Irish public and the Connaught peasantry, owe a full meed of thanks to Mr. O'Connor Power, M.P., for having elicited a debate on Irish sanitation which will prove of infinite benefit to the cause of sanitary reformers in Ireland, and which cannot fail to have made Parliament aware that the administration of public health law in that country is about as incompetent and ineffective as possible, and that the state of the dwellings of the average Irish peasant is simply indescribable. We give such portions of the debate as have reference to the sanitary condition of the people.

Mr. O'Connor Power called attention to the Reports of Dr. Nixon and Dr. Wodehouse presented to the Irish Local Government Board, and to the Reports of Dr. Sigerson, Dr. Kenny, and Mr. J. A. Fox, presented to the Dublin Mansion House Relief Committee, on the condition of the fever-stricken districts of Mayo. The hon. member said that the condition of the dwellings of the labouring classes in many parts of the West of Ireland was of the most dangerous character. He regretted that this matter had apparently escaped the attention of English members, for no paper had been laid on the table of the House during the present session more worthy of the attention of the members of the House. Dr. Nixon found 46 families, with a population of 140 persons, living in a most wretched condition in cabins filled with cattle and pigs, whose food was almost exclusively Indian meal without milk. In another place on the mountain side he found a family living in dirt with eight inches of manure on the floor, and where the woman of the house explained that she could not clean it out because there was no manure heap. Further on he spoke of three typhoid fever patients being tended in one room, in which there were three cows, a quantity of chickens, three cats, and a large dog. Some time ago it was shown that there were 94,000 one-roomed huts in Ireland, and over half a million of the population were living in the manner described in these Reports. The Reports of Dr. Sigerson, Dr. Kenny, and Mr. Fox, who visited these places on behalf of the Mansion House Committee, confirmed the official reports. These gentlemen said that the fevered people were practically allowed to lie in their hovels. With regard to the remedies to be applied, if the instructions already given by the Local Government Board to the local authorities were being properly carried out, that was a great point gained. He had no faith, however, even in the independent action of the boards of guardians with reference to measures for improving the condition of the people, especially with respect to sanitary arrangements. There was a strong obstructive party to be found in every one of those boards. So far as the sanitary arrangements in agricultural dwellings

were concerned, it seemed that the boards of guardians were greatly at fault in not having enforced the provisions of the Public Health Act, and it rested with the Local Government Board to stimulate them to do what was necessary. The hon. member concluded by moving: "That in the opinion of this House the present condition of the agricultural population in Mayo, Sligo, and other parts of the West of Ireland demands the serious and immediate attention of her Majesty's Government; that effective sanitary arrangements should be carried out in those districts under the authority of the Local Government Board; that it is essential, with a view to preventing the spread of contagious disease, that a change of nutritious food should be given to all persons receiving relief under the Poor-law, or under the system substituted for the Poor-law in certain localities, and that a competent medical staff should be organised without delay, and distributed over those parts of the country visited by fever."

Mr. Sexton, as representing one of the two counties which had suffered most severely from want, and from epidemic which had been the direct consequence of want, remarked that the boards of guardians in the West of Ireland were not fit to be entrusted with the administration of the Poor-law in the present crisis.

Mr. O'Donnell endorsed the suggestion that the administration of the Poor-law should be reformed, and the manner of electing Poor-law guardians improved, so that the latter body might be more representative than it was at present.

Mr. Forster said the hon. member for Mayo had made an interesting and a moderate statement—a statement that was not overcharged in any respect; and what he felt in listening to it was a sort of melancholy satisfaction that, as a result of the calamity and distress of this year, a very strong light would be thrown upon the condition of the people in certain parts of Ireland. The sanitary arrangements were, no doubt, another cause; in fact, it was surprising to anyone who had read the reports to find that when once the fever had got into those districts it had not spread more, and he could only account for the fact on the ground that the people had become, so to speak, acclimatised to the condition of things in which they had so long lived. The fever had decidedly decreased in every district, and he hoped and believed they had got over the stringent emergency of the crisis. An hon. member had suggested that the Local Government Board in Ireland should issue compulsory bye-laws. He would point out that the law could not go much in advance of public opinion, and that it did not therefore follow that what might be possible in England would be in any way possible in Ireland. He did not suppose that any fresh arrangement of the machinery would really cure the unsanitary grievance. The causes were more deep-seated than to be removed by a mere election of guardians—strongly as he disapproved of the present mode of election. (Hear.) He was extremely jealous of interfering with local management, believing it to be one of the reasons of England's greatness, and although sometimes and for the moment the central government might do a thing better than the local body, yet, in the end, local management would be found greatly superior. The only reason why he asked that the other portions of the Resolution should not be pressed was because he thought it might be interpreted as a condemnation to some extent of the Local Government Board in Ireland, which he imagined the hon. gentleman did not mean it to be, and also because, if the subject was to be fully considered, the Resolution did not embrace all the issues concerned.

Dr. Lyons thought that any sanitary reform or any sweeping reform of the dwellings of the poor was not to be thought of. Such a reform must be brought about gradually. He advocated the establishment of depôt hospitals in small towns, as a means of dealing with epidemic visitations. In such hospitals the people could be better attended to than in their own wretched homes.

We select one phrase spoken by the Chief Secretary as our text for comment on this subject. The right hon. gentleman says that "He does not suppose that any fresh arrangement of the machinery will really cure the unsanitary grievance." We answer this statement by the assertion which we make upon the authority of the proceedings of the Irish Local Government Board recorded within the last three years in these columns, that under the existing law it is impossible that the executive could remedy the insanitation of Irish peasant dwellings, and, moreover, that the Irish Local Government Board, under the direction of its late Vice-President, Sir Alfred Power, deliberately and intentionally arranged the law in this form because they did not desire either the trouble or responsibility of enforcing the Irish Public Health Act. When the revision of the law was under discussion by Select Committee, Sir Alfred Power testified that he had no inspecting staff such as exists in England for sanitary work, but he did more; he resisted in every way the proposal to provide the Board with such a staff, and elected to throw the public health law to the boards of guardians, and leave them to put it in force or not, just as they please. Needless to say that the great majority of these boards—being by tradition and by personal interest impelled to resist sanitary improvement—did absolutely nothing. In every step which they might have taken to administer that law efficiently, the Irish Local Government Board obstructed and discouraged them, and every remonstrance of the medical profession and of Irish sanitary reformers was met by them with open hostility or covert resistance.

The existence of that state of the dwellings of the peasantry of the West which the medical reports have disclosed—a state which exists in almost equal flagrancy throughout Ireland—is the natural and inevitable result of the fact that the Irish Local Government Board has no knowledge nor any means of knowledge as to whether any individual sanitary authority or its officers are discharging their duty. Before the appointment of these special commissioners, the department which is responsible for Irish public health was, in all probability, totally innocent of information as to the sanitary state of the fever-stricken district, except that they must have known that the state of affairs disclosed in the reports of these commissioners exists more or less all over Ireland. They knew, and know full well, that many, if not most, of the sanitary authorities in Ireland pay to their health officers a nominal salary, with the tacit instruction to those officers to give as little trouble as possible about the existence of dirt and disease within the district, and with this knowledge the Local Government Board neither asks for nor would desire to be supplied with the means of inspecting these districts and supervising the administration of public health law within them.

We deny most emphatically, and repudiate most earnestly, the statement which Dr. Lyons, M.P., is reported above to have made, for a long experience of the working of sanitary law in Ireland assures that a thorough reform needs only a little quiet energy and perseverance, and that both sanitary authorities and peasantry have readily conformed to the necessary orders when encouraged to do so. We appeal to the quarterly returns of the Irish Registrar-General for confirmatory evidence on this point, and we

without hesitation accuse the Irish Local Government Board with having for years past withheld the necessary encouragement. For the abominable state of affairs narrated by Mr. O'Connor Power, neither Parliament, nor the Ministry, nor the boards of guardians, nor the medical officers are responsible. It is to the proceedings of the Irish Local Government Board, and to no other cause, that the breakdown of the Irish sanitary system is due.

ARMY MEDICAL UNIFICATION.

In alluding to coming changes in the *personnel* of the Army Medical Department, a contemporary remarks that "the acerbities caused by the carrying out of unification have been toned down." In so far as a few officers are concerned who are themselves in the enjoyment of comfortable appointments, the remark is no doubt true; but we hesitate to believe that it is so with regard to the majority—those who, less fortunate, do the heavy work of the department, and are moved about from one station to another "according to the requirements of the service." But it is not so much in relation to individuals, as to the general interests of the service, that we desire to look at this subject. If, then, we consider it from this point of view, what do we find to be the case? We learn in the first place, that what is described as a new and improved *system* is but a reversion to a state of things which, having been found insufficient for the requirements of war as far back as the beginning of this century, and being then looked upon as no system at all, had to be so completely metamorphosed as to all intents and purposes to be abolished. In the second place, there has occurred nothing, so far as we have been able to ascertain, in the working of the unified *system*, either in Africa or in Afghanistan, to recommend it in substitution of the old *double* system, in which regimental and *general* establishments worked in unison, and—when properly equipped—well. But with regard to the ordinary requirements of soldiers, their families, and officers in garrison, not alone does it appear from information which has reached us that under the present state of things matters are by no means satisfactory, but that in not a few instances recourse is being had to private practitioners rather than to the medical officers of the *stations*, for there would appear now to be none appointed to the distinct charge of distinct bodies of troops. In all such instances, the officers or others who apply to private practitioners have, it may be safely presumed, to pay for advice, and afterwards for medicine, so that, especially with such as are married, a very heavy tax is thus added to those that have heretofore helped to reduce in amount the mere pittance in the shape of pay upon which those without private means of their own have to support the pomp and circumstance of their position.

But there is reason to believe that the interests of officers and men suffer in another and more vital manner, as a result, more or less direct, of a "system" under which, on foreign service, more especially in the tropics and India, medical officers are so frequently moved about that continuous experience has become almost a thing of the past. This is a phase of the question to which for the present we prefer to allude only in this very general manner, but it is one to which, if we are not much mistaken, the attention of the authorities must before long be directed, if indeed it has not already been so.

Notes on Current Topics.

Sanitary Work in Dublin.

In his last report to the Public Health Committee of the Dublin Corporation, Dr. Cameron, the Medical Superintendent Officer of Health for the city, details the steps which have been taken under his direction for the disinfection of fever houses, and the hints which he gives may be noted with advantage for the instruction of health officers generally.

In addition to the disinfection of rooms in Dublin in which cases of contagious diseases have occurred, the rooms and the articles in them are now thoroughly washed—carbolic acid soap being used—by charwomen. Strong women, above the ages at which contagious diseases are likely to be contracted, are employed for this purpose. Chemical disinfecting, lime-washing, and thorough scouring with soap and water, ought to remove the contagious matter from infected rooms. As these processes require some time to thoroughly perform them, Dr. Cameron expresses his strong conviction that shelters for the families whose rooms are undergoing purification should be provided. This suggestion has been more than once made to the Committee, and it is one of the recommendations set forth in the report of the Royal Sanitary Commissioners.

Amongst the houses closed as being unfit for human habitation Dr. Cameron mentions one of them was closed under peculiar circumstances. This house is large and in good repair. It contains twelve rooms, each of which is a separate dwelling or tenement. The inhabitants of these twelve tenements numbered nearly fifty persons. Within a period of two months, eight cases of typhus fever occurred in this house. It was evident that it was saturated with typhus poison, and that it could not be purified properly until detenanted. As each room was occupied day and night by a family the conclusion was come to that when the house came to be re-opened, the number of separate tenements should be reduced from twelve to eight.

The influence which an improved condition of their dwellings has upon the health of the people is shown in a remarkable manner. Dr. Cameron found certain cottages with earthern floors, damp, and below the level of the road; ill-ventilated rooms, tiny yards, with filthy privies placed up against the houses. The people complained of the discomfort of their dwellings. Illness was never absent from these cottages, and chest and rheumatic affections appeared to predominate over other classes of disease. He made minute inquiries in reference to the health of these people, and found it extremely unsatisfactory. The cottages were, last autumn, thoroughly repaired. Since then, not a single admission into hospital from these cottages has taken place; and the improvement in the health of the inmates is quite remarkable.

Dr. Cameron finds at this date there are occupied as

dwellings, 134 stables, and he certifies that they are unfit for human habitation when placed under the following conditions :—When the stables in which animals are kept are unceiled ; when there is not a separate entrance into the part of the premises occupied by human beings ; when the rooms are too small, badly ventilated, or out of repair ; when there is not proper sanitary accommodation provided for the occupants. A large number of stable dwellings have been closed.

The Action of Salicylic Acid and Salicylate of Soda on the Respiration.

THE experiments of Dr. C. Luin (*Tribune Médicale*) have shown him that the action of salicylic acid on the respiration is a complete one. Under its influence the respiratory strength undergoes changes according to the period of the observation and the doses of the remedy ; diminution with small doses, augmentation with large doses. The carbonic acid undergoes similar modifications, diminution under small and augmentation under larger doses. These changes are unquestionably of central origin, and it is in the respiratory nervous centres that we must seek the most probable explanation of them. MM. Bochefontaine and Chabert showed that one of the properties of salicylic acid was to diminish the reflex actions of the bulbo-medullary grey substance ; consequently the substance penetrating the torrent of the circulation would act very promptly on the properties of this substance and thus diminish the respiratory reflex. This will explain the initial slowing and at the same time the diminution of carbonic acid. But under the influence of larger doses the substance accumulating in the cerebro-spinal fluid acts directly on the roots of the pneumogastric, and by this excitation, slight at first, causes an acceleration of the respiratory movements, similar to that produced by feeble excitation of the central ends of the pneumogastrics ; but the excitation always increasing, after great acceleration, the respiratory movements soon begin to get slower and slower, and lastly, the excitation reaching its maximum, they stop under the influence of the great excitation of the pneumogastrics ; hence the asphyxia which always occurs in animals submitted to experimental doses of salicylic acid. What are the therapeutic conclusions ? These experiments show that in small doses salicylic acid is a substance which may really be of service, but one must always mistrust too large doses, which not only cannot be borne by some, but which are in themselves more hurtful than beneficial.

Inebriate Asylums.

IN their report recently presented to Parliament the Irish Lunacy Inspectors say, with reference to the Voluntary Self-confinement Act for Inebriates passed in 1878, that not a single person in Ireland has practically adopted the clauses of that well-intentioned statute. In the first place, the primary obligation of an applicant to assert uncontrollable indulgence in the use of spirituous liquors will never obtain with women, who are the greatest offenders ; and in the second, very few, indeed, if even one, will seek for a sort of imprisonment, an escape, or attempted escape from which would be a misdemeanor.

Comparative Lunacy Statistics of England and Ireland.

THE Inspectors of Irish Lunatic Asylums publish in their recent report some interesting general observations on the extension of lunacy in the United Kingdom. In their report for 1878 the English Commissioners supply a very valuable and interesting table. It appears from it that in 1879 the registered insane of all classes and denominations amounted to 69,885, in a general population of 25,165,386 ; 62,107 of them being located in public institutions, whereas in 1859, or twenty years prior, out of a population of 19,686,701 there were only 36,183, or little more than a half similarly circumstanced. If, since then, insanity had only extended *pari passu* with the increase of population, 46,200 in round numbers would now represent the lunatic element.

In 1868 the census of England and Wales reached 21,946,713, when there were exactly 51,000 patients between their private and public establishments for the insane.

As regards sex, in 1859, females labouring under mental affections numbered 19,006 as against 16,756 males ; similarly in 1869, 28,813 as against 24,366 ; and in 1879, 38,202 against 31,683, while in the general population there was scarcely a numerical difference between them.

In Ireland, dating ten years later, that is from 1868 (and we apprehend an analogy would hold good during the previous decennial period), there were 9,454 registered lunatics, setting down the inhabitants at the full figure of 5,760,000. Unlike, however, what has long obtained and still continues in England, the male have been uniformly far more numerous with us than the female insane, or nearly in a surplus ratio of fifteen per cent, as regards public asylums alone.

January last, the registered of both sexes under our supervision amounted in a population of 5,412,000 to 12,819, of whom 8,490 were maintained in district asylums. At the same time there were in English county and borough asylums 38,871, so far then as the respective population of the two countries is in question, the number of insane in either, who benefit by the Treasury rate in aid, is almost in equal proportions.

Regarding the amount of insanity as quoted at the two decennial dates, viz., from 1859 to 1869, and then to 1879, a rather close approximation is noticeable in its progress. It would seem in both countries to have nearly doubled in the course of twenty years, or less than a generation, substantially, however, more in England than in Ireland, where, with a decreasing population, it might reasonably be expected to decline. Did the diminution of the inhabitants here depend on natural causes alone, the inference would be correct, but when largely owing to emigration, the decrepid in mind, no less than in body are left behind. Hence a disproportion results between the sane and the insane, the latter being in excess. As it is, however, the registered insane in England Wales stand comparatively with those in Ireland in the ratio of 7 to 6¼, according to the latest statistics.

The inspectors see no reason to suppose that lunacy is actually on the increase ; various causes tend to bring its existence—occasionally indeed, it might be said its presumed existence—into light, but notably the establishment

of well organised receptacles for the treatment of mental affections, now, so well understood that longevity in asylums is almost proverbial.

The Differential Diagnosis between Laryngeal Syphilis and Laryngeal Phthisis.

Dr. Moure, of Bordeaux, in his graduation thesis, recently published, has carefully studied these two affections, especially in reference to their differential diagnosis, founding his conclusions upon numerous and careful observations.

He divides his work into two parts; in the first part he considers briefly other laryngeal affections, such as diphtheritic, stridulous, œdematous, and catarrhal laryngitis, in order to show clearly the points of difference between them and the two affections specially under discussion. In considering them in the second part he first considers the symptoms common to both phthisis and syphilis of the larynx, and then those that are different in the two affections. Thus in the secondary period of syphilis we have erythema, roseola, mucous patches, inflammatory hyperplasia, paralysis and dysphonia; in the tertiary stage tubercles, syphilomata, ulcerations, caries, necrosis, and syphilitic vegetations.

In the case of laryngeal phthisis, the course of which the author divides also into two periods, we meet with (1) in the catarrhal period, catarrh and erosions resulting from it, congestion, inflammatory swelling, and aphonia; (2) in the ulcerative and necrotic period, tuberculous infiltration, ulcerations, vegetations, and lastly, œdema.

All these symptoms being placed side by side will aid us in drawing a sure diagnosis between syphilitic and phthisical affections of the larynx.

Rötheln.

The question whether the affection known by this name is a distinct disease, or only a hybrid of measles and scarlatina, is one scarcely quite decided. A correspondence which has been going on for some time in the pages of a weekly contemporary shows that the profession is divided upon the point. An article appeared in the *Edinburgh Medical Journal* for last month by Mr. Douglas Hemming, of Bournemouth, in which the distinct nature of the affection is upheld. Mr. Hemming quotes the opinions of authorities who have previously written on the subject, and also speaks from cases which have come under his own observation. The principal points of diagnostic difference which he makes between Rötheln and measles and scarlatina are as follows:—1. The temperature rarely rises above 101° or 102°. 2. The eruption in Rötheln appears at once all over the body. This is an almost constant peculiarity. 3. Rötheln affords no protection against measles or scarlatina, and *vice versâ*. 4. Rötheln propagates itself, and never gives rise to either measles or scarlatina. 5. The eruptive patches in Rötheln are raised above the surrounding skin, particularly towards the centre of the patch where the colour is also deeper. 6. The degeneration in Rötheln is in fine branny scales. 7. The patches of eruption in Rötheln are larger and brighter in severe cases than in mild ones. 8. The tongue is dirty at first, then strawberry like, and finally smooth.

The New Sydenham Society.

The excellent work being done by the New Sydenham Society is progressing very favourably. The Report presented at the twenty-second annual meeting announces the probable publication for the current year, which comprise—1. A third fasciculus of the Society's Lexicon (already out). 2. The fifth and concluding volume of Hebra's Treatise on Skin Diseases, with index to the whole (already out). 3. Koch's Researches on the Etiology of diseases consequent on Wound Infection. 4. A third fasciculus of the Society's Atlas of Pathology, comprising diseases of the Liver. 5. A fourth fasciculus of the Lexicon. The Report then continues: "The Council has adopted, for reprinting, the classical Treatise of Dr. Stokes on Diseases of the Chest. This work, which has been always held in very high estimation by all authorities, has been for some time out of print. It will be edited for the Society, with short annotations, &c., by Dr. Hudson, of Dublin. It has also been decided to edit for the Society a selection from the works of Duchenne; and Dr. Vivian Poore has, at the Council's request, undertaken the preparation of the work. The translation of Prof. Charcot's Lectures on the Diseases of Old Age, and on certain Chronic Maladies, has been decided on. The work has been placed in the hands of Mr. Wm. S. Tuke. The preparation of the Society's Lexicon is in the hands of its editors, Mr. Power and Dr. Sedgwick, progressing satisfactorily and as rapidly as the difficulties of the task permit. Three fasciculi have been issued, and another is just ready. It is to be distinctly understood that the fasciculi of this work are always issued as soon as ready. The Council is prepared to devote to it any portion of the year's income that may be requisite; and nothing but the onerous nature of the editors' task will be allowed to delay its publication."

The Use of Physiology.

Dr. Michael Foster's address on physiology, delivered before the British Medical Association at Cambridge, should command the attention of everyone interested in the influence this study exerts over the training of the medical student. As a means of educating the mind to an accurate scientific apprehension of the significance of observed facts, the data of physiology, and the consideration of their bearing on vital economics cannot be too highly rated. It is not right longer to regard the mere acquisition of certain definite details of function, as that which must be learnt by the physiological student, but it should be accepted that the special science he deals with is to be a future aid to him in the decision of questions concerning complicated and wide-spreading derangements. Dr. Foster's appreciation of the real importance of physiology will find increased acceptance as there arises a truer sense of the actual bearing of this branch of knowledge to the others which enter into the medical curriculum. No longer subordinate to anatomy, it holds in the highest intellectual centres, a position of no inferiority, but is accorded the dignity due to it as the key to all that is most vital in treatment, and most essential in diagnosis. The method by which it is taught, moreover, calls for the revision the best teachers loudly demand; and we may possibly hope without a misplaced confidence, that in the

future physiology will assume its real position as the handmaid of medicine.

The Bennett-Stanford Prize.

SOME time since we announced that a prize of £100 had been offered by Mr. J. V. Bennett-Stanford, for the best essay on "Hydrophobia: Its Nature, Prevention, and Treatment." The duty of adjudicating the award was accepted by the Royal College of Physicians, and the report of the examining committee having been presented, the successful essayist is M. Bourrel, of Paris. There were nineteen essays sent in, and in addition to the one receiving the prize, a second, bearing the motto "*multorum annorum opus*" was highly commended by the examiners, who regretted the fact that there was no second prize with which to reward its author. Mr. Bennett-Stanford has offered £10 towards the sum of £50 to be subscribed for the purpose, which it is to be hoped will be accomplished. The arrangements for publishing the successful essay have not been made as yet, but it is to be hoped that something will be done to bring it before the profession at an early date.

Daring Frauds.

DURING the past few months some unprincipled person or persons have been perpetrating a series of well-conceived and most daring frauds. These consist in forwarding to professional and lay papers communications, purporting to be from a gentleman who is a student at St. Bartholomew's Hospital, but which, we are assured, in no single instance have been written by him. An attempt was a few weeks since made on us, but we were able to verify our suspicions of the *bona fides* of the communication sent to us, which, the same identically, has been successfully palmed off on the *Lancet*, and finds a place in the current number of that journal. We regret also to find that our usually accurate contemporary, *Nature*, has been similarly imposed upon, a letter appearing in it this week, apparently from the same hand, and bearing the same forged signature. That an occurrence of this kind should be possible is very much to be regretted; and it is to be hoped the perpetrator of what is really a criminal act may be speedily discovered and fittingly punished.

Benzoate of Soda.

ACCORDING to Müller of Breslau (*La Presse Médicale Belge*), benzoate of soda is not antiseptic. It has no action on bacteria, and does not prevent infection. Urine, to which from 1·50 to 20 per cent. of benzoate of soda added, and fresh meat soaked in solutions of 1, 5, 10, and 20 per cent., decomposed; the 20 per cent. solutions seemed somewhat to retard the appearance of the phenomena of decomposition, Benzoate of soda conducts itself very much the same as salicylate of soda. These salts have neither antiseptic nor antiputrescent properties. This is not the case with benzoic or salicylic acids, both of which have these properties in a high degree. It results from this that the action of these salts varies considerably according to the plan of absorption. In the stomach they are decomposed by the hydrochloric acid: salicylic acid and benzoic acid are set free, and may act locally as antiseptics.

The Treatment of Ulcers.

MANDELBAUM (*La Presse Médicale Belge*), advises in old ulcers of the legs, scraping, followed by the application of iodoform. When new granulations are formed, a plaster of mercurial soap may be applied, fixed by means of a bandage.

DR. WARD, the late M.P. for Galway, left Southampton by the Royal mail steamer for British Guiana. He has accepted a Government appointment on the medical staff of the colony. The plantation doctors are appointed by the Home Government, and are entirely under their control. The manager or owner of the plantation, to which the medical men may be designated, has no power to displace them. The salaries are paid out of the colonial revenue, according to a graduated scale, and range from £600 or £800 a year to £1,500 or £2,000.

THE annual death-rate from the seven principal zymotic diseases averaged 7·8 per 1,000 in the principal large towns, and ranged from 2·1 and 3·9 in Wolverhampton and Bristol, to 14·1 and 15·2 in Leicester and Salford. Scarlet fever showed the largest proportional fatality in Sunderland and Bradford. Small-pox caused 6 more deaths in London, 4 in Dublin, but not one in any of the other large towns. Two fatal cases of diphtheria occurred in Plymouth, Manchester, and Salford. The deaths referred to diarrhœa in these towns, which had been 577 and 711 in the two preceding weeks, further rose to 807.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

REGISTRAR-GENERAL'S REPORT.—According to the weekly return of births, deaths, and marriages for the eight principal towns of Scotland, the death-rate for the week ending with Saturday, the 14th inst., was 20·1 per 1,000 of estimated population. This rate is 4·8 above that for the corresponding week of last year, and 0·3 above that for the previous week of the present year. The lowest mortality was recorded in Paisley, viz., 15·9 per 1,000; and the highest mortality in Leith, viz., 24·0 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·9 per 1,000, nearly the same as the rate for last week. An increase occurred in the number of deaths from scarlet fever in Leith. Acute diseases of the chest caused 70 deaths, being 3 more than the number for the previous week.

MORNINGSIDE ASYLUM, EDINBURGH.—Dr. Charles Johnstone, some time medical assistant at the Fife and Kinross Asylum, has been appointed to a similar position in the Morningside Asylum, Edinburgh.

COUPAR.—Dr. Keith Macdonald has been appointed surgeon to the Prison, Coupar.

DEATH-RATE OF GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 14th inst., were at the rate of 20 per 1,000 per annum, against 21 in the preceding week, and 15, 21, and 22 in the corresponding periods of 1879, 1878, and 1877.

HEALTH OF EDINBURGH.—For the week with Saturday, the 4th inst., the deaths in Edinburgh numbered 80, equiva-

lent to the annual mortality of 18·21 per 1,000. Of the persons who died four were above 80 years of age, and three above 90 years.

Literature.

THE HYPODERMIC INJECTION OF MORPHIA. (a)

Some time since, Dr. Kane, of New York, addressed a circular, through the medium of the medical journals, to the profession, relative to the hypodermic injection of morphia. Three hundred and sixty-eight answers were received, and on these, together with information the result of "personal inquiries and letters," the work now before us is based. Although the material thus collected is given to the reader in a very raw condition, it is, nevertheless, quite apparent that the author has bestowed considerable time and trouble in arranging his correspondence in a form in which it might be readable. If he had paid more attention, however, to selecting the lengthy quotations and compressing his matter into a considerably less space he would have had ample material of a useful and valuable nature to have carried out his original intention of making two or three interesting journal articles. In order to make the subject extensive enough to form a book, a great deal in the nature of filling-in matter or padding has been introduced. In many instances the details given are very meagre, and as often cases are reported only on hearsay, the conclusions drawn therefrom are of very little value. For these reasons we apprehend that the work in its present condition, being little more than undigested correspondence, will add little to our present information on the subject of which it treats, nor will the author's notes founded thereon materially alter the present opinion of the use of a hypodermic injection of morphia.

Perhaps we should best meet the wishes of our readers by giving a brief outline of the work.

The first chapter commences with the history of the subcutaneous method of administering drugs. This method, as is well known, was almost simultaneously discovered by Dr. Alexander Wood, of Edinburgh, and Dr. Rynd, of Dublin.

With regard to the doctrine of localisation, with which this portion of the work also treats, the author writes: "From a consideration of various arguments *pro* and *con*, it would seem that localisation is only to be had recourse to for a single or a few injections." This certainly is not our experience. There can be no doubt that in many cases, as, for example, a case of sciatica, local injection is of much service.

The second chapter is given up to accidents attendant on the use of the hypodermic syringe. It is difficult to reconcile the different results reported by Dr. Kane's correspondents. One gentleman has had abscesses formed in one out of every *ten* punctures; while another says, "in a practice of twenty years in which I have used the hypodermic syringe many thousands of times, I have seldom had inflammation, and never abscesses." The author writes, "of the 357 physicians who answered my questions 28 reported absceses as common, 69 as rare, and 213 have had none."

The third chapter deals with idiosyncracies and egotisms. The author thinks a dose of morphia for hypodermic use "in commencing should not exceed one-third of that ordinarily administered by the mouth." Professor Wood reports having seen a case very nearly fatal from one-sixth grain. Other similar cases will be found in this portion of the volume, and at page 98 we have mention of a patient sleeping twenty-four hours after one-twelfth of a grain.

The fourth and fifth chapters treat of the more severe accidents, alarming syncope, and death. We cannot help thinking that the accidents narrated in these chapters were invariably caused by the needle being inserted into a vein. There is no doubt to inject a solution of morphia into a vein is a very serious accident, but to do so, in our mind, shows that the operation has been very carelessly performed. The author gives a simple rule by which this accident may in all cases be avoided: if, when the needle has been introduced under the skin, the piston be drawn in a little, if the point be in a vein blood will be drawn into the syringe. It would be well in our judgment to adopt this simple precaution. Dr. Kane writes, "I think no physician should be free from blame in case of accident where he had not a ligature or tape loosely encircling the arm above the point of puncture; at the first indication of danger this should be drawn tight and kept so for several hours, being loosened gradually, thus permitting but gradual entrance of the drug into the circulation."

We cannot agree with the author in the necessity for this precaution. We ourselves have used the syringe thousands of times and have known it to be used at least ten times that number without the smallest accident. We are strongly of opinion that if the needle be introduced with care, so that its point be not in a vein, there is no danger whatever. Dr. George Oliver believes that all danger is done away with by inserting the needle perpendicularly to the surface and passing it well in.

The sixth chapter gives the treatment of opium narcotism.

The seventh chapter treats of the "convulsive and tetanising action of morphia on man," as also with cases of tetanus produced by "rusty or unclean needles."

The eighth chapter discusses the advantages or otherwise of using atropia with morphia. The majority of Dr. Kane's correspondents do not use it.

The next chapter treats of the morphia habit. One hundred and thirty-one physicians report 184 cases, and 197 physicians have never seen a case of this kind. Opium-eaters must be rather common in America when we have one gentleman reporting that in two years he treated 800 cases of opium inebriety in one hospital.

The last chapter is given up to conclusions. In summing up the author says of the hypodermic method, "its value in cases specially suited to it cannot be over estimated; its use in cases unsuited to it or where other means would answer as well cannot be too heartily and strongly condemned."

THE ORGANIC CONSTITUENTS OF PLANTS AND VEGETABLES. (a)

The above is a work of compilation, but still one of great utility, and one of very considerable research. A slight error has crept in in the heading of the second part, which is called "Molecular Weights of Organic Compounds." It is really only a list of the organic substances with their formulæ. To arrive at their molecular weight it would be necessary to perform in each case a calculation. This list, however, we are informed, differs frequently from the text, and where such differences occur they are the results of recent investigation. It is most desirable that we should possess such a list.

AN INTRODUCTION TO THE PRACTICE OF COMMERCIAL ORGANIC ANALYSES. (b)

The title of this work is a very modest one, considering that the volume before us is merely the first instalment, and deals only in the cyanogen compounds, alcohols and their derivations, phenols, and acids. Mr. Allen is one of the most energetic of the public analysts in England, and is therefore one of those men who treats his subjects from a practical, and not a theoretical, point of view. There are, perhaps, not half-a-dozen chemists in the whole of the United Kingdom who would be justified in attempting such a book. Its scope is ample, as it professes to be a treatise "on the properties, proximate analytical examination, and modes of assaying the various chemicals and preparations employed in the arts, manufactures, medicine," &c. (*sic*), with concise methods for the detection and determination of their impurities, adulterations, and products of decom-

position. Mr. Allen states that most of the processes given have been personally verified; also that many of the results copied from book to book for the last thirty years have been found to be worthless, and in such cases they have been rejected. In these days of book compilation such a statement is quite refreshing, and we believe, from the author's great practical experience, that such is quite true of his work. We have only one objection to the book before us, which, after all, is a debatable point. The attempt to arrange a purely technical work on a basis of scientific classification is, we think, a mistake. It can present so few facilities for reference, and, therefore, nothing is gained.

University of London.—First M.B. Examination. Examination for Honours :—

ANATOMY—First Class.

Cooper, George Fredk. St. Thomas's Hospital*

Third Class.

Evans, C. S., St. Thomas's Hosp. | Horrocks, W. H., Owens College
Moline, P. F. University College | Norvill, F. H. King's College
Martin, S. H. C., B.Sc., Univ. Col.

NOTICES TO CORRESPONDENTS.

Dr. Haughton.—The letters came to hand too late to be noticed in the present issue. They shall receive careful consideration; but on a rough survey, there seems scarcely ground for publication of the whole correspondence.

Caritas.—Very. Charity is the distinguishing virtue of the present age, and in our profession it is the most conspicuous of all the amiable qualities that mark a medical man. The higher we ascend the more charitable we become, the more forbearing and considerate for others. The Americans mistake us, of course.

VACANCIES.

Children's Hospital, Birmingham.—Assistant Resident Medical Officer. Salary, £40, with board, &c. Applications to the Secretary not later than Sept. 1.

Flintshire Dispensary.—House Surgeon. Salary, £100. Candidates must be conversant with the Welsh language. Applications to the Hon. Sec. on or before Sept. 7.

Huddersfield Infirmary.—House Surgeon. Salary, £80, with lodgings. Applications to the Hon. Sec. not later than Sept. 1.

Islington Workhouse and Infirmary.—Resident Medical Officer. Salary, £200, with furnished apartments. Also Resident Assistant Medical Officer and Dispenser of Medicines. Salary, £100. Applications to to the Clerk on or before Sept. 1.

New Ross Union, Fethard Dispensary.—Medical Officer. Salary, £100, with fees. Election, Sept. 7.

Newry Union, Mountmorris Dispensary.—Medical Officer. Salary, £120, with fess, and £15 as Medical Officer of Health. Election, Sept. 6.

North Eastern Hospital for Children.—House Surgeon. Salary, £70, with board and lodgings. Also a Registrar. Salary, £50. Applications to the Secretary not later than Sept. 1.

Preston and County of Lancaster Royal Infirmary.—Senior House Surgeon. Salary, £120. Applications to the Secretary on or before Sept. 1.

Wolverhampton Union.—Medical Officer. Salary, £80. Applications to the Clerk to the Guardians on or before Sept. 2.

APPOINTMENTS.

Brown, A. S., M.R.C.S.E., L.S.A., House Surgeon to the Warneford Hospital, Leamington.

Elliott, H., M.R.C.S.E., L.S.A., House Physician to the North Staffordshire Infirmary, Hartshill, Stoke-upon-Trent.

Finegan, A. D. O'C., L.K.Q.C.P.I., R.C.S.I. L.M., Assistant Medical Officer to the St. George's-in-the-East Infirmary and Workhouse.

Forsyth, R., M.D., C.M., Medical Officer of Health for Drighlington, Yorkshire.

Frazer, G. B., M.R.C.S.E., L.S.A., Honorary Medical Officer to the West of England Sanatorium.

Hacon, W. E., L.R.C.P.L., M.R.C.S.E., Resident Medical Superintendent of the Christchurch Lunatic Asylum, Canterbury, New Zealand.

Hall, Mr. T. L., House Surgeon to the Bridgnorth Infirmary and Dispensary.

Hayes, T. E. D., L.K.Q.C.P.I., M.R.C.S.E., L.S.A., Medical Officer to the Hawkhurst District of the Cranbrook Union.

Jacob, E. H., M.A., M.D., Honorary Physician to the Leeds Fever Hospital.

Kenny, J. B., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Killeshandra Dispensary, Cavan Union.

Marsh, C. J., M.R.C.S.E., Medical Officer for the Second District of the Yeovil Union.

Vlieland, C. J., M.R.C.S.E., L.S.A., House Surgeon and Secretary to the General Infirmary, Hertford.

Wright, A. H., M.D., Associate Lecturer on Physiology at the Toronto School of Medicine.

Births.

Barry.—Aug. 5, at Thurles, co. Tipperary, the wife of M. J. Barry, L.R.C.I., of a son.

Davidson.—Aug. 17, at Priory Row, Coventry, the wife of C. Davidson, M.D., of a son.

Goodhart.—Aug. 12, at Hervey road, Blackheath, the wife of J. F. Goodhart, M.D., of Weymouth Street, Portland Place, W., of a son.

Grimshaw.—Aug. 14, at 13 Molesworth-Street, Dublin, the wife of T. W. Grimshaw, M.D., of a son.

Mackesy.—At Waterford, the wife of Ald. G. I. Mackesy, M.D., J.P., of a son.

Power.—July 30, at Borrisoleigh, co. Tipperary, the wife of J. Power, L.R.C.S.I., of a son.

Stevens.—Aug. 16, at High Street, Stoke Newington, N., the wife of A. Felix Stevens, M.D., of a daughter.

Marriages.

Ward—Leonard.—Aug. 20, at Margate, M. F. Ward, M.D., to Ellen, only child of the late Robert Leonard, Esq., of Norwich.

Deaths.

Henry.—June 8, at Penola, South Australia, Alexander Donaldson Henry, M.B., T.C.D., L.R.C.S.I., aged 34.

Herbert.—Aug. 11, at Markyate Street, near Dunstable, Jonas T. Herbert, L.R.C.P.Ed., L.R.C.S.Glas., aged 39.

Davis.—Aug. 16, at Conie Brae, West Malvern, Henry Davis, M.D., F.R.C.S., formerly of Putney, aged 70.

Murray.—July 10, at Peshawur, Punjab, India, Charles H. Murray, M.R.C.S.E., Surgeon, Bengal Army.

Pratt.—Aug. 10, at Mountnorris, co. Armagh, Thos. Pratt, M.R.C.S.E

AN ANALYSIS OF FIVE HUNDRED CASES OF PERFORATION OF THE MEMBRANA TYMPANI. (a)

By GEORGE P. FIELD,
Aural Surgeon to St. Mary's Hospital.

(*Continued from page* 86.)

Among other effects produced there were 58 cases of perforation with incurable deafness; that is, where no improvement had taken place from treatment. Scarlet fever here, again, is the most productive cause; 29 patients, 4 of them with loss of hearing in both ears, 14 from injury, 1 double, 6 from cold, 3 from measles, 1 from small-pox, and in 4 it was not known how the deafness occurred. Of these 58, 38 of them were totally deaf in one ear, and 5 in both.

And now I come to other sources of evil-producing perforations. There was 1 patient from croup with a perforation in both ears; 2 from scarlet fever and measles combined, 1 being double; diphtheria, 1. In this case very rapid mischief had taken place. Pain is not severe, for the acute stage passes into a virulent chronic form of otitis, and the bone rapidly becomes necrosed.

If, therefore, we get in diphtheria ear symptoms, puncture of the drum head is the only means we have of preventing the terrible gangrenous inflammation that is likely to follow, by allowing a free exit for pus, and so effectually stopping the rapid destruction of tissue likely to occur. (b)

Three cases in typhoid fever, and 1 in typhus. The acute inflammation in these diseases runs the same course as in the virulent exanthematous forms. The pain is severe at night only, and after the membrane has given way. At early morning we get a discharge of thin, serous, colourless fluid, which, after a time, changes to a creamy-looking discharge, with entire loss of pain. Early treatment is especially called for.

Then comes 1 case after ague, 1 double perforation from mumps, 3 after small-pox, 1 double (4 perforations).

I believe the origin of the mischief in small-pox, as in scarlet fever and measles, is in the throat, and extends through the Eustachian tube to the ear.

Two cases said to have arisen from syphilis. I have a patient with double perforation now under my care at St. Mary's. J. H., æt. 22, a pawnbroker's assistant; all treatment utterly failing to aid him until I put him on anti-syphilitic remedies. I prescribed 5 grs. of iodide of potassium 3 times a day, and he quickly lost the discharge, and the tympanic membranes, although perforated, assumed a healthy aspect. There is no special appearance to be noted, as far as I have seen, in syphilitic disease of the membranous tympani. The second case I shall come to presently.

I find only one out of the 500 from phthisis, and 16 are said to be due to "abscess;" 2 patients from convulsions. In one of these, a little boy, both drums were perforated.

W. F., æt. 8½, was brought to me at the hospital, Oct. 11, 1879. His mother stated that twelve months previously he ate a biscuit with some poison on it, that had been placed in the garden for the purpose of poisoning a dog. Soon afterwards he was seized with violent convulsions, both drum heads gave way, and he had considerable hæmorrhage from the ears. A thick discharge had been running from both ears since, and he had become deaf and dumb—quite unable to hear any sounds. I have now been treating him for seven months. I saw him again lately. The discharge, which was at first of a most offensive nature, has entirely left him. This desirable result was obtained (1) from the use of often changed astringent lotions and powders; (2) from counter irritation behind the ears; (3) from paying great attention to the general health; and (4) from the application of

(a) Read before the Harveian Society, May 20th, 1880.

(b) There is another rare form of disease in which, after the purulent form has lasted some time, there is an increase of pain, and the appearance of a white diphtheritic membrane, which adheres most closely to the inflamed structures. It is usually found in scrofulous subjects."—*Burnett*, 269.

Politzer's bag regularly twice a week. The employment of Politzer's process is especially beneficial, for by "mixing air and lotion within the tympanum thus, with the subsequent use of the syringe, the cavity becomes in time thoroughly cleared of its contents of viscid or purulent secretions, and old perforations, if not of very great size, will often heal. It is desirable sometimes to touch the edges of the orifice with nitrate of silver." (Hinton.) The perforations in this case have both remained, but the boy is gradually but slowly regaining his hearing.

Another case (sent to me by Dr. Morton) I saw last year at the hospital; it was that of a little girl, æt. 12, who was supposed to have become deaf and dumb after scarlet fever. The mother had been told so over and over again, but I said to myself I will regularly clear out the tympanum by means of Politzer's process, and I did so with the other treatment I have mentioned, and she, too, has gradually recovered speech and hearing.

I have had several others of a like nature; one under my care now of great promise, lately sent to me by my friend, Mr. Edmund Owen. I am sure much may be done for some of the so-called deaf and dumb. I am sorry to say they are hardly ever given a chance, for it is customary, I believe, to say, "Oh, deaf and dumb, take it away," and all treatment is habitually neglected. Only a few weeks since at the hospital a woman said to me, "Three years ago, sir, you told me not to despair; my child might hear." The same treatment I have mentioned has been carried out; the boy has been occasionally brought, and I have often told her I was afraid it was no good, but she would persevere, and a short time since she said to me, "The child can hear, sir; and what is more, he can talk."

I remember in the early part of this year seeing some remarks in one of the medical journals by a French surgeon, Dr. Bonnafont, on this very point.

Four years ago Mr. Philps, of Peckham, sent me a so-called deaf and dumb boy, æt. 9, who had lost his hearing five years before after scarlet fever. He has by very slow degrees regained his hearing, and could a month ago say many little words.

Then I find in the list two women from cold after confinement; 3 cases from myringitis, or acute inflammation of the drum head alone. This is a very rare disease, as usually the tympanum on the one side, or the external auditory meatus on the other, are implicated. The perforation seems to begin from the outside; the membrane is intensely red, and the hearing is not so much affected as where the tympanum is diseased. The most common cause of this malady is sudden cold, such as that brought on from taking a header into cold water.

I see that 8 patients out of the 500 have suffered from perforation of the drum head from bathing, but in all cases the tympanum as well as the drum head was thus involved. In one, a lady sent by Dr. Randall, who three years previously had ruptured the membrane in brushing her hair, from running a hair-pin, which had somehow become attached to the brush, into her right ear, again ruptured the same membrane from taking a header into the sea, and which I had the satisfaction of closing again for her. I had also another patient who twice ruptured the same ear by taking a header into the sea, who on both occasions I was fortunate enough to cure. Plugging the ears with cotton wool before bathing will always prevent injury.

Two patients from whooping-cough. In these there is generally an accumulation of mucous in the tympanum, and the membrane suddenly gives way from mechanical pressure on a distended mucous membrane during a fit of coughing. Some of these later cases almost belong to Part 2, Perforations of the Drum Head from Injury.

These are a much more satisfactory class of cases to deal with, for traumatic ruptures are apt to close much more readily than those caused by disease, as I will presently show. Out of the 500 I have had 80 patients—12 double, or 92 perforations—from accidents, 11 from falls on the head—4 double. Other injuries to head, 30 patients—1 double. Boxing the ears, 8 patients—2 double, making 10 perforations, out of the 500 cases. This is a large percentage; and just a few words on this objectionable practice. All the patients were boys who had received the injury at school from the hands of their tutors. Several of the lads are permanently injured; 2 of them very deaf in both ears, and several more or less disabled for life. This is not the only form of correction administered about the ears at schools; there is a novel treatment that boys call knuckling, which is likely to cause rupture of the membrana tympani; I had two cases lately. I will endeavour to describe the operation for the benefit of school boards. Place the boy's head under the left arm, double up the right fist, projecting the second joint of the index finger, then bring the knuckle forcibly in contact with the boy's external auditory meatus, and if it is well done it will probably induce hæmorrhage from the ear. I have been told that this is an ingenious German method of punishment lately introduced into this country.

In the nineteenth century it is disgraceful that such a barbarous penalty should be still enforced in our schools. Boys will be boys, and I do not altogether blame the schoolmasters, for they are not aware, I suppose, that such serious mischief may take place simply from concussion of air forcibly driven inwards on to the drum head; but it is high time they were taught.

From other blows on the head, 16 patients, 2 double; forcing pen-holder into ear, 1; forcing hair-pin into ear (I have already mentioned), 1; injury from foreign bodies, 4; kick from horse, 1; blows on the head from cricket ball, 2; injury from football, 1; fall of flower pot on head, 1; 1 case of perforation in both ears; violent sneezing, 2.

(To be continued.)

GENU VALGUM. (*a*)

By OSMAN VINCENT, F.R.C.S. Ed.

As it is my intention to make these lectures eminently practical, I shall avoid as much as possible, except for the thorough understanding of the subject, any mention of the various views propounded by numerous authors for the last thirty years on the cause and treatment of knock-knee, but endeavour practically to prove to you, and, I think, convince you, through the medium of your common sense, the true nature of the complaint we are considering, and its proper treatment. I propose to limit my remarks to the acquired form of knock-knee, as the rickety variety will necessarily come under consideration in my next lecture among rachitic deformities. Let us first glance at the anatomy of the joint. The knee-joint is a hinge joint formed by the articulating surfaces of the femur and tibia, kept in apposition by external and internal ligaments. Those mostly involved in the deformity before us are external, to the joint the lateral, internally, the crucial. The former governing the extension and flexion of the joint, the latter to check what little rotation the healthy knee-joint is capable of; and it must be borne in mind that rotation of the joint cannot be made, but in the flexed or semi-flexed condition of the limb, and consequently when the lateral ligaments are in the greatest state of relaxation.

This accounts for the curious disappearance of the deformity, when the patient, "the decubitus being dorsal," flexes the legs on the thigh, and the thigh on the pelvis. In this position the inner ankles can be brought into direct apposition, although before, with the limbs extended, they were several inches apart.

Observe also the greater length of the inner condyle, when compared with the outer, the bone being held perpendicularly. Now, as the centre of motion is the centre of gravity, and the centre of gravity in man is a moveable

(*a*) A lecture delivered at the National Hospital for the Deformed.

point, limited in the variation of its position between the pubes and sacrum, it necessarily follows that when the balance is disturbed the above-mentioned fact operates largely in aggravating and continuing the deformity. Acquired genu valgum may vary from the slight tilt necessary to counter-balance a wide pelvis to the extreme deformity of nearly a right angle with the femora. These severe cases now are happily rare, owing to the better knowledge of the subject by the practitioner, and the better education of the parents, who are slowly beginning to distrust the dictum of the kind friends, who tell them that they (the children) will grow out of it. I may here remark, *àpropos* "of growing out of it," that such cases have never come under my notice; and among the out-patients here for the last nine years, I have had the opportunity of seeing a vast number of knock-knees, and am, therefore, qualified to speak, and I have also the authority of the Father of orthopædic surgery in this country, my esteemed colleague and friend, Dr. Little, who states in his work on "Deformities," "I have been consulted concerning many patients with the highest grade of this affection (genu valgum) in whose early infancy their parents were assured the "weakness" and deformity would spontaneously subside, that the children would, in fact, grow out of it. I advise you not to trust implicitly to nature in these cases. When once the straight line is, to any extent, destroyed by this inward inclination of the knees, the assistance of art is imperatively required for its relief." But to go back to our subject.

1st. *The Causes.*—Acquired knock-knee in the earliest and simplest cases that come under our notice, occurs when the fond mother, having had more confidence in the food that man has proposed, rather than that which God has ordained, puts her child, age 10 to 12 months, upon the ground, and teaches him to walk with any amount of adipose deposit, but little or no phosphate of lime; what can you expect but that the super-incumbent weight of the body being too great a strain on the internal lateral ligament, the first stage towards genu valgum is begun.

This is the genu valgum of the first dentition. The next class of cases occurs in boys and girls (particularly boys) whose previous life and bringing up has been such as to fit them by their thoroughly unhealthy and debilitated state for the production of any deformity, and being allowed to be on their feet running about the street from "morn to dewy eve," and even midnight, some kind of curvature of the legs will most certainly take place, and I am inclined to give the preference to genu valgum.

This is the genu valgum of the second dentition. The next class of cases occurs in adults, such as bakers, smiths, warehousemen, and others, who have many hours on their feet, and carry heavy weights on their heads or shoulders; also the youths and girls employed in the large shops of the metropolis and other big towns, and who are often on their feet fourteen, sixteen, or even more hours at a stretch. This, combined with the fact that the surroundings are most unhealthy "in the way of bad ventilation, overcrowding, and inferior food," and also that the larger number of these young people come from the purer air of the country, are just at, or about the age of puberty, and therefore, more liable to favour any deviation from nature's laws, it is not to be wondered at that after a few months' exposure to these adverse circumstances the signs of impaired nutrition from imperfect assimilation becomes evident. From these external causes, combined with the constant super-incumbent weight, the lower extremities suffer, and knock-knee results, commonly associated with its step sister, "flat foot." Having thus glanced at the various causes which produce genu valgum, let us see what happens in the joint should the mischief be allowed to continue.

The internal ligament slowly but surely gives way until the knees touch each other or even cross, and the feet cannot be brought together without stooping the body or bending the knees. The internal condyle of the femur becomes in a parallel line prominent, the external often to a certain extent absorbed. At the same time the tendon of the biceps as well as the lower edge of the vastus externus become very distinct. In fact, the biceps by its action helps to increase the deformity, after the leg has assumed a certain degree of angularity; and, as a rule, the arch of the foot yields to the superincumbent pressure. This assemblage of malpositions, slow at first, increases in proportion as the feet diverge, for the strength of the column of support afforded by the lower extremities passes away *pari passu* with the increasing obliquity in the direction of the femur and tibia. There is sometimes pain, often to a considerable extent, in the joints, from the stretching of the soft parts, but there is always a feeling of weakness, after a time becoming so great that the sufferer has to relinquish his usual employment to seek relief.

Genu valgum is generally double, that is, both knees implicated; but a single knee may be affected, generally from accident or rheumatic arthritis weakening the joint, and the deformity of one knee may reach an extreme degree, the leg being everted almost to a right angle with the thigh, the opposite member remaining straight. Whenever there is inequality of the two limbs or a strong irregularity in the gait, there will be either some degree of lateral curvature or an unnatural flexibility of the vertebral column, or both combined, arising from the constant efforts made by the patient to preserve the proper balance; but as this lateral curvature is only compensatory, we must look for its cure, or at least its amelioration, when the cause is removed, and the inequality in the length of the limbs adjusted.

We may here ask, are the changes which take place in the articulating surfaces (for change there certainly is produced by the prolonged displacement of the bones)—are these changes permanent? I am disposed to think not.

Nature is always too glad to assist the surgeon should he go with her, and not in direct opposition to her laws; and when we, by removing the pressure from the oppressed condyle, relaxing the overstretched internal lateral ligament, and stretching the lax external ones, bring the joint as near as possible to the normal state, we find a ready helper in the conservative dame. Then when the bones have been set straight, does the patient regain the proper amount of strength and comfort, and I have seen several cases of 17 and 18, after eighteen months or two years' treatment, able to leave off supports, a circumstance which would have been impossible had the proper direction of the articular surfaces been permanently altered.

So much for the causes and effects of genu valgum. Let us turn to the treatment, which, after all, is the most interesting part, and which, if properly conducted, will bring honour and profit to the surgeon and patient alike. I propose first to describe the treatment we pursue here, and afterwards glance at the much vexed question of osteotomy.

The treatment here we will divide into three parts:—

1. The removal of the superincumbent weight, which tends to increase the deformity.
2. The straightening of that already existing, and
3. The constitutional treatment.

1*st. The Removal of the Superincumbent Weight.*—In the infant, if the deformity is slight and discovered early, this is all that need be done, and with children under six, who have no resources for the purpose of amusement, is best accomplished by keeping them in bed. They are then tolerably safe and out of mischief. I may here remark that not only does it seem an accepted opinion of the great mass of the public, but with members of the profession itself, that remaining in bed destroys health and is "so weakening," but the prejudices against this treatment have arisen from the fact that patients are generally sent to bed with a weakening disease upon them, and when the period of convalescence approaches they attribute to bed that weakness and debility which is the consequence of the complaint for which they were consigned to it, and not the confinement to the bed itself. Six weeks rest in bed with

frictions and manipulations is all that is required for this class of cases ; but one word on the kind and mode of application. They can best be employed by making a fulcrum of your own knee placed between those of the patient, the power being your hands holding the legs at the ankles, and the weight the resistance of the contracted tissues. But even with this simple but effectual method great care must be taken that during its application the leg be kept straight and the toes looking directly upwards, otherwise rotation would occur at the knee, and we should do more harm than good.

The mechanical treatment of the second class I mentioned consists (unless severe) of rest and the application of long outside splints, with or without knee caps of webbing, depending on the severity of the case, and it must be borne in mind that it is next to useless in cases of single knock-knee to apply the splint to the affected leg only, as without the controlling power of a splint on the sound leg by means of the back strap, that on the deformed one has a constant tendency to twist over or ride upon the anterior surface of the limb ; but with the back strap properly adjusted such "riding" is rendered impossible. Together with the application of splints, manipulation and friction should also be used to prevent as far as possible that loss of nutrition which is inseparable from a limb in a constant state of bandage ; and a most important part of the treatment in all forms of the complaint is the passive motion of the knee-joint, which may be made by placing the child or adult on the table and making him swing the legs for a few minutes daily, in order to overcome the stiffness caused by the more or less fixation of the knee-joints.

In considering the treatment of the third class of cases, we include those neglected ones which have been allowed, from various causes, to assume the greatest possible degree of deformity.

Putting aside for a few minutes the question of the desirability or non-desirability of operative interference, and looking upon these cases as possible to be dealt with by mechanical means alone, we shall find that the best way of gaining our end is by what is called the trough-splint, which is an apparatus of either tin or wood, designed to fix the femur and lower leg and foot, and then by a rack and pinion acting on a strong knee-cap, exercise sufficient force to gradually reduce the deformed leg to its normal condition. This splint will require to be worn for from three to twelve months, according to the amount of deformity to be reduced, the age of the patient, and the consolidation of the bones—the elasticity and amount of contraction of the soft parts to be overcome.

Although slight cases may, when the leg shall have regained its normal straightness, be allowed to walk without mechanical supports, yet, as a rule, in severe cases they will be required for two years after the treatment by rest and splints has reduced the deformity to a proper degree of straightness, and until the articular surfaces have become adapted to the change in their relations, and until the muscles have regained their proper functions.

The constitutional treatment of knock-knees should be that of any debilitated state, combined with that usually needed for deficient earthy material in the bones—viz., iron, iodine, cod-liver oil, quinine, and sea air ; and as regards diet, restriction in the quantity of fluids, increase of animal food, and especially fatty materials.

The question of the division of the hamstring tendons, or at least the biceps, has often been argued. I am of opinion that it is a step to which recourse should not be had as being very rarely necessary, except in severe adult cases ; and, thanks to the better knowledge of the nineteenth century and the stride orthopædy has made, these severe adult cases are now but seldom seen. And again, so great an authority as Dr. Little himself classes such division among the "unnecessary orthopædic operations."

Given sufficient time, I believe any tendon or structure contracted by malposition or *external* influences, and not by nervous irritation, will yield to mechanical extension [illegible] and constantly applied. Still, section of the biceps is a proceeding which may give important assistance with ordinary precaution, is free from risk, and saves the patient's time by a few weeks, which is often a consideration, especially in those cases which, by force of circumstances, are obliged to gain their own living, or are dependent on precarious assistance.

Osteotomy for curvature of bones is not at all a new operation. Louis Stromeyer, Little, formerly one of the surgeons to this hospital, operated in this room, in the year 1867, for severe anterior curvature of the tibia, with a very good result, but it was not until quite lately that the femur has been divided for the relief of genu valgum.

Mr. H. Taylor, of Guildford, in October, 1876, divided this bone transversely above the condyles, for a case of knock-knee, with advantage ; reported in the *Lancet* of that year.

Mr. Barwell and Dr. McEwen last year had a paper war in the same journal, as to the priority of their various *procedures* for the cure of this deformity by the removal of a wedged-shaped piece of bone.

Professor Ogston's subcutaneous section of the internal condyle is above all others the one least open to objection. He opens the joint in performing this operation, but it is so thoroughly subcutaneous that no ill consequences have been found to follow.

But now comes the important question : Is so severe a procedure warranted by such an easily treated deformity ? Which of us would like our knee-joints opened, however subcutaneously and antiseptically, with all the steam power of carbolic spray and Listerian germ destroyers ? Would we not rather for ourselves and our children adopt the treatment which I have laid before you, no doubt imperfectly, but with a firm belief, founded on no small experience, that it is the best, the most applicable, the safest, and the most satisfactory ?

Proof being everything I will bring forward two cases in support of my statement, both being fair examples of at least twenty so treated without the aid of the saw and chisel, during the last twelve months.

E. H., æt. 11 ; severe genu valgum ; an otherwise healthy girl—when standing 11¼ inches between malleoli. (Fig. 1.) Trough splint applied Dec. 22, 1879, and worn night and day with manipulations and friction.

Fig. 1.

January 19th, 1880.—Much impoved, 6½ inches between ankles.

March 16th.—The ankles now touch, but another month is considered advantageous for the treatment.

In the end of May this year walking instruments were applied, and the last I heard of the case was that she could stand and walk with properly straight legs (fig. 2), and I am confident after a few weeks' sojourn at the seaside, she will next year be able to leave off the supports.

FIG. 2.

H. H., æt. 15; seventh out of eight children, others all healthy. Born in the country and nursed twelve months. Has passed safely through all infantile diseases. On coming to London to reside six years ago he soon felt the change, and began to get "weak at the knees." His mother sought advice, and was told he would "grow out of it," but as usual in these cases that prophecy was vain. He was then occasionally treated with long splints, but with little result, owing to the treatment being only half carried out.

In May 1879 he was brought to me on account of the inconvenience of locomotion. He was a thick set, strong built lad, well developed for his age. No history of struma, and no rachitic affection of upper extremities or trunk. As he stood with his knees touching there was 9 inches between the inner ankles. The knee-joints were large and the feet somewhat flat.

I ordered trough splints and complete rest for three months.

The splints were applied on June 6th, and worn night and day. With the exception of some slight synovitis during the first weeks, due to the over-zealousness of the mother and the patient in keeping the knee-caps rather too tight, the case progressed favourably and quickly, and on the 15th August he was ready for his walking instruments, being able to place his knees and ankles in close apposition.

On the 9th September the instruments were applied, uprights to hip with fixed joint at the knee and knee caps, and he was allowed to walk round the table.

Two months after this (Nov. 10th) he can walk about all day without fatigue, and hold a coin between his knees and ankles while standing erect, without his instruments.

In all probability in a few months he will leave off his supports and be a straight-legged useful member of society.

The woodcuts are taken from photographs taken by Mr. Holloway, of Anerley, S.E.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Brighton 16, Bristol 16, Edinburgh 17, Glasgow 20, Wolverhampton 20, London 21, Portsmouth 22, Oldham 22, Norwich 23, Bradford 24, Birmingham 24, Newcastle-upon-Tyne 24, Leeds 26, Nottingham 29, Sheffield 29, Liverpool 30, Sunderland 30, Manchester 31, Salford 33, Leicester 35, Plymouth 35, Dublin 38, and the highest rate 40 in Hull.

Clinical Records.

EXTENSIVE EXTRAVASATION OF URINE OCCURRING TO A PATIENT, ÆT. SEVENTY-NINE—SUCCESSFULLY TREATED,

By JAMES GILLESPIE, L.R.C.S.I.,
Clones.

ON Sunday morning, the 4th of November, 1877, I received a note at 7 a.m., from Lisnaskea, a town some nine miles distant, requesting my immediate attendance upon a gentleman there stated to be suffering from retention of urine.

Upon arrival at his residence I found my patient, a man of large frame, very corpulent, and aged, as I was informed, about 79 years, calmly lying on his back in bed quite free from pain, or distress of any kind, although appearing somewhat weak. I was told that during the four days previous to my visit he had passed no water whatever. Originally of robust constitution, and active habits—travelling about a good deal too—he had always available and enjoyed the comforts of good living. With the exception of a few slight fits of the gout, I could not learn that he had ever suffered any serious illness.

A fortnight or so before the commencement of this urinary derangement he had given up his custom of taking a tumbler or two of whisky punch every evening.

Upon examination, the pulse was found irregular and intermittent, numbering 103 beats in the minute, the tongue moderately moist, clean, and pale; surface of body rather cool. No distension of bladder could be felt by introduction of finger into rectum and tapping above pubis, but a doughy swelling was palpable all over the iliac, hypogastric, and lower portion of umbilical regions The extremity of penis was scarcely perceptible, the organ being almost completely buried in an enormously distended and gangrenous scrotum—purplish black in colour. The perinæum presented a swelling of the same character as that on the abdomen, but not extending laterally or posteriorly beyond this space.

Careful review satisfied me that urinary extravasation had taken place—most probably the result of a rupture of the urethra occurring behind an old stricture: the attachment of the middle and superficial layers of perinæal fascia to the rami of the ischia and pubes, and their posterior connections sufficiently accounted for its limitation here.

The feet, ankles, and lower thirds of legs were swollen, and pitted on pressure. I was now proceeding to operate, when a bystander suggested the assistance of Dr. Sandels, living in the town. This gentleman having agreed as to the necessity for immediate operative measures, and the patient being placed in as convenient a position as possible at the edge of the bed, I commenced by dipping a Liston's bistoury for two-thirds the depth of its blade into the upper part of the scrotum, about an inch to the left of the median line, and swept it obliquely downwards and inwards through the entire extent of the swollen mass, carrying the incision through the root of the scrotum into the perinæum. A similar incision was then made on the right side meeting the extremity of the first one at an acute angle. A good deal of thickish urinuus fluid, with a little pus, escaped from the wounds, which were then dressed with strips of lint saturated with turpentine; there was no hæmorrhage of any account. The penis having now become accessible was hooked forward, the prepuce slit, and with considerable difficulty a small bulb-ended catheter passed through a stricture into the bladder.

Unwilling to tax our patient's strength farther, and in the hope that what had been done would prove a sufficient drain for the extravasated fluid, we ordered barm poultices to be applied, gave him a dose of tincture of iron, and put him on strong beef tea, with a glass of grog every third hour, during the day-time, and port wine *ad libitum* at night.

Next day, Nov. 5th,' upon examining the scrotum we could plainly see that the tunica vaginalis testis had escaped without injury: it was gathered up closely under the penis like a small purse, its parietal layer being slightly rough, and of a dirty yellowish white colour. The swelling over abdomen still persisting and the patient feeling pretty strong, an incision upwards and slightly outwards about 2½ inches long, and commencing an inch or so above crest of right pubis was made into it, but without the result expected, nothing but a deep layer of fat becoming visible. Charcoal and barm poultices were now applied, quinine with full doses of tincture of iron ordered, and the beef-tea, grog, and wine continued.

Upon the 6th his general condition was not so favourable.

On the 7th he was suffering severe constitutional disturbance: a great angry welt of a dusky red colour extended across umbilicus from one lumbar region to the other, while towards upper part of left iliac region, a minute hole appeared, through which, upon the slightest pressure, a dark, thin pus flowed copiously. The introduction of a probe demonstrated an immense abscess, occupying the greater part of the seat of the doughy swelling before referred to. A director being entered at the hole as a guide, the anterior wall of the abscess was slit through its whole extent transversely, with a sharp-pointed bistoury; this incision nearly met the upper extremity of the one over the pubis: after a few days the intervening tissue sloughed, and they communicated, giving the anterior wall of the abscess the appearance of a large triangular flap. A considerable quantity of dark pus escaped from the abscess, which was then together with the other parts implicated, plentifully syringed with tepid water, and after that, with a tepid solution of hyposulphite of soda, ʒj. ad. oj. A carrot poultice, and a couple of compresses. secured by a bandage, completed the dressing.

From this time the condition of the patient steadily improved: the abdominal abscess and sloughing scrotum were everyday carefully syringed with tepid water, followed by the solution of hyposulphite of soda; the latter leaving nothing to be desired as an efficient, cleanly, and manageable anti-zymotic.

On the 15th Nov., the lower two-thirds of scrotum had sloughed away, or been removed, and we now drew the remaining parts together gently with silken sutures, commencing above.

Dec. 6th, saw the abscess healed.

By the 22nd December the scrotum had healed entirely; a fistula, however, communicating with the ruptured urethra, and through which the urine flowed, and the index finger could be passed, remained open behind it.

The case having thus far progressed satisfactorily, the cure of the stricture with a view to subsequent occlusion of the fistula was next attempted.

On the 28th December a No. 1 bougie was got through it, and on January 1st a No. 10 black gum bulb catheter passed into the bladder. Upon oiling, and introducing my left fore-finger into the fistulous opening, I could now estimate the extent to which the floor of the urethra had been destroyed; by feeling that portion of catheter in the channel, which after its passage into the bladder remained bare to my touch: this amounted to about an inch. The instrument was tied in, and left without a spigot, in order to secure, if possible, the passage of the urine through it.

Sir Henry Thompson writing on Urinary Fistulæ in Holmes's "System of Surgery," second edition, vol. iv., page 985, says:—"It is better to withdraw all the patient's urine by introducing a catheter three or four times a day, or more frequently if necessary. When the patient can do this cleverly for himself, and thus insure at every want to pass urine during a period of several weeks that it is carefully removed without contact with the urethra, a most successful result may be hoped for. I have had an instance of this under my own care, where a large portion of the floor of the urethra being lost, the opening closed after three or four months' attention to his practice."

Circumstances preventing this preferable course, a catheter was retained in the bladder almost continuously, viz., for the following periods.

From 1st to 4th January. From 4th to 6th January. From 6th to 8th January. From 8th to 15th January. From 16th to 23rd January. From 23rd January to 2nd February. From 6th February to 20th February. From 23rd February to 9th March.

On the 13th March a selection of catheters was given to his attendant, with directions to draw off the urine four times a day, or more frequently if requisite.

It may be proper to mention here, that from the 23rd January, in addition to the catheterism, an india-rubber ball inflated with air was worn in the perinæum during the daytime, the patient sitting in a chair, and proved very efficient in keeping the fistulous orifice closed.

Commencing on the 26th January various, substances were applied to the fistula, viz., perchloride of iron, the sulphates of copper, zinc, and iron, the nitrate of silver: all these both in solution and in the solid form; the latter yielded by far the best results, at first with the pencil, and when the track became smaller, with the powder introduced in the groove of a director.

Upon the 16th March, by keeping the point of a finger upon the opening, the patient could urinate in a full stream through the meatus urinarius.

At what proved my last visit to him on the 29th March, and before applying the nitrate of silver, I found the fistulous opening so small that it would hardly admit the point of a crow-quill. He now presented a very good scrotum, patched up from the remains of the old one, and only differing in appearace from it by its smaller size.

I may here state that the œdema at first apparent in feet, ankles, and legs, extended upwards into the thighs during the progress of the case, and gave great trouble. It was treated by a few incisions—1½ inch—and punctures, with warm bathing and careful bandaging. A small anthrax on the back of the left thigh was also dealt with.

The relative agents administered internally were preparations of iron, quinine, bark, opium, strychnia, sulphuric acid, alcohol, beef tea, singly or in combination, the two former always, and in as full doses as could be borne. Towards the close of treatment the daily allowance of alcohol was reduced to three-fourths of a wine-glassful of whiskey made into punch.

The catheters used varied from Nos. 4 to 10 of Weiss's scale, and were mostly gum-elastic. It is worthy of remark that their presence did not at any time occasion either irritation of the bladder or suppuration in the urethra, nor did they ever become loose in this channel. This I think may in a great measure be fairly attributed to the iron, opium, quinine, and strychnia part of the treatment.

The urine was entirely voided through the instrument, none passing from the fistula, at which sometimes a drop or two of muco-pus appeared.

Some criticism having been provoked by the retention of a catheter in the bladder and urethra for such lengthened periods, it was comforting to find the same practice confirmed by such an eminent authority as Dr. Wheeler, of the City of Dublin Hospital, who, in a paper read before the Surgical Society of Ireland, and appearing in the columns of the *Medical Press and Circular*, of February 6th, 1878, page 110, gives the following account:—"One interesting case I will briefly state: It was that of a gentleman, on whom I operated for several urethral perinæal fistulæ. Mr. Butcher, Mr. Tufnell, Dr. Benson, and Dr. Harley were present. In this case I eventually closed the last unhealed opening of the urethra by passing a pin from one side to the other, approximating the edges by a figure of 8 suture. *I was obliged to keep in a catheter for twenty-seven days.* He had much ropy mucus; in truth, it was as excessive as one suffering from an aggravated attack of chronic catarrh. I gave him pareira brava and washed out his bladder with

sulpho-carbolate of zinc, as is my plan in these cases. He was relieved of his distress and mucus, and I was enabled to retain the cathether in his bladder till I believed it might safely be withdrawn."

The bladder in this case was not washed out, the catheters never became covered with deposit and the mode of securing them adopted was by a woollen thread tied behind glans-penis.

Two or three days subsequent to my last visit the patient travelled to Dublin, and since that time he has gone about everywhere as usual. I met him last year at a distance from home in a neighbouring town, walking firmly and unattended over a rough cobble-stone foot-path.

Upon frequent occasions up to March last, I have seen him walking briskly about and evidently in fair health, which, I have been informed within the last few days, still continues; but I have not learned whether the last application of the nitrate of silver effected the final closure of the fistula. I presume, however that it did.

The very advanced age of the gentleman who suffered from this terrible accident, and his recovery, notwithstanding the circumstances of delay at the outset, with other points of interest in the case sufficiently obvious, invests it, I venture to hope, with a degree of importance warranting me in thus laying it before the profession.

P.S.—Since writing the above I have been informed that occlusion of the fistula was not completed by the last application of the nitrate of silver; but I have no doubt that it would now require little further treatment to prevent it giving any more trouble.

Translations.

DEAFNESS: ITS DEGREES, CAUSES, AND THE VARIOUS MEANS RECENTLY DEVISED FOR DIMINISHING ITS INCONVENIENCES. (a)

By Dr. LADREIT DE LACHARRIERE.

Translated by W. DOUGLAS HEMMING, F.R.C.S.Ed., Bournemouth.

(*Concluded from page* 158.)

The fleshy granulations which are developed in the tympanum are often the origin of polypi; but it must also be remembered that these little tumours whose histological composition varies with their situation may be primarily developed without being preceded by otorrhœa. In this development they fill the tympanum and are not slow in making their way through the membrane. Such a lesion causes considerable deafness mechanically, by obstructing the passage of the sound waves and by provoking an inflammatory condition of all the organs of the middle ear. The tympanum may also be the seat of hæmorrhage, and the blood may either exude from the surface of the mucous membrane or come from the nasal fossæ. To be collected in the tympanum the hæmorrhage must take place at the orifice of the tube, but most often the blood passes into the ear when the nasal fossæ are tamponed. The blood continuing to flow in a space hermetically closed by the plugs, experiences a pressure which forces it into the neighbouring passages. We have often seen hæmorrhage of the tympanum due to this cause alone. Most frequently, however, wounds cause this accident. Sometimes a blow or a fall causes a fracture of the petrous bone, at other times there is direct lesion of the tympanum by a pointed body. I had under my care a colleague who injured his tympanum by a penholder with which he was scratching the meatus; and last year a lady who wounded herself under similar circumstances with a knitting-needle. In both these cases abundant hæmorrhage was produced in the tympanum. Everyone knows that artillerymen suffer from hæmorrhage when they fire very heavy guns without taking the precaution of well closing their ears with cotton-wool. In these cases it is the concussion of atmospheric air which causes the rupture and the hæmorrhage; almost complete deafness is always the consequence. It is more or less lasting according to the time when it comes under treatment. We must not count on the disappearance of the blood-clots; it is better to open a way through the membrane and empty the tympanum, as then we shall avoid the fibrinous deposits which may originate adhesions causing almost incurable lesions.

The affections of the middle ear indicated above cause alterations in the chain of ossicles interfering with their play. Triquet (a) has well described ankylosis of the ossicular chain. It may be present in different degrees. In incomplete ankylosis, we find a simple hypertrophy or thickening of the mucous membrane, often plastic thickenings in the form of indurations and inflammatory in origin. Complete ankylosis is characterised by fibrous expansions or calcareous or bony deposits. It will be understood that the degree of deafness will be in proportion to the extent of the lesion and the immobility of the chain. Herpetic affections of the ear may be propagated to the tympanum and to the organs which it contains. Engorgement of the chain of ossicles due to this cause alone may be frequently observed. The membranes which are always more or less affected in these cases always lose some of their transparency. They are slightly dull and thickened.

Chronic thickenings of the ossicular chain may also be observed without any neighbouring lesion. They are most often caused by the gouty diathesis. The handle of the malleus shows notable thickening and appears like a whitish vertical streak, the promontory is more projecting, sometimes the handle of the malleus is abnormally vascular, and appears on the membrane like pannus on the cornea. The membrane preserves its ordinary physiological conditions. Very often its aspect alone will allow us to recognise the primary cause of this lesion. This form of deafness is almost always hereditary. We know of gouty families all the members of which present in different degrees the same lesions of the ossicular chain.

Whatever may be the lesion of the chain and whatever its degree, its inevitable consequence will be more or less marked cophosis, feeble sound waves being unable to set the ossicles in motion or penetrate to the labyrinth. This form of deafness is most often accompanied by tinnitus of a whistling character, which may be explained by slight compressions of the fenestræ.

The form of deafness which has the most serious characters is undoubtedly that caused by a lesion of the labyrinth. It may be the result of a wound, either from a fall or a blow on the head. Under these conditions the deafness is almost always absolute and incurable. Some years ago I treated without any result a working gilder who on a frosty day fell on his head and was carried home unconscious. When he recovered he was totally deaf and could only be communicated with by writing. The middle ears were intact; the deafness could only be explained by a lesion of the labyrinth.

In the course of severe fevers, particularly of typhoid, there is often a certain degree of deafness accompanying the stage of prostration or the delirium. Sometimes the loss of hearing is complete and irremediable. We annually receive into the National Institution a number of children whose deafness is due to no other cause.

The herpetic diathesis and malarious influences may also cause labyrinthine trouble and deafness. In these cases this is generally not complete, and is accompanied by affections of the vaso-motor nerves, characterised by congestive pulsations in the ear and its neighbourhood, and most annoying tinnitus. Patients complain of whistlings, noises of bells, and most varied musical sounds. Some neuroses, such as migraine, are accompanied by analogous morbid phenomena. The auditory trouble is sometimes characterised by a very exaggerated impressionability of the hearing. The tinnitus produced by sulphate of quinine may be explained similarly by a transitory congested condition of the labyrinth.

We cannot terminate this somewhat lengthy enumeration of the causes of deafness without mentioning Ménière's disease.

This is always characterised by vertigo and deafness. The malady described by Ménière manifests itself by a sudden

(a) "Annales des Maladies de l'Oreille, du Larynx," &c. 1880.

(a) "Leçons sur les Maladies de l'Oreille," p. 122.

onset of vertigo and absolute deafness. On post-mortem examination one finds serious lesions of the labyrinths, particularly hæmorrhage. Now-a-days, the range of this disease is somewhat extended, and under its name are included some affections of the labyrinth which are characterised by vertigo and tinnitus, but in which deafness is only relative or transitory.

The account I have just given of the causes of deafness will show how many difficulties stand in our way in appreciating the progress, making a prognosis, and devising methods of treatment for this infirmity.

It will be understood how often our efforts are powerless against such diverse and numerous changes.

Until lately, we have only endeavoured to lighten the weight of the infirmity by the use of trumpets and hearing tubes; trumpets are of very ancient origin, and I do not propose to consider them now. Hearing tubes are of more recent date and have lately been brought to great perfection. They consist of a tube, to one extremity of which is placed a cup of horn, and at the other a nozzle which the patient places in the ear. The tube is made of silk and indiarubber, is very simple, and a good conductor of sound. Mr. Rein, of London, who is very skilful in this manufacture, has made for me tubes three metres long and three centimetres in diameter, dividing into numerous branches, allowing deaf persons who cannot hear the voice at a distance, to take part in general conversation, and to enjoy the charms of music. For the latter purpose it is sufficient to place the receiving cup into the case of the piano.

The hearing tube is certainly the most useful instrument which we possess, but it is irksome to use, cumbersome when large, and only allows conversation with a small number of persons. We can understand then the favour and delight accorded to inventions announced as capable of restoring the deaf to the delights of life. Some of these inventions are remarkable only for the impudence of their claims; of these we shall say nothing, they deserve but oblivion; others have attracted the attention of learned bodies, and such marvellous properties have been accorded to them that it is necessary to mention them, and bring them down to their due level of merit.

All audiphones are based upon the principle, that in persons whose acoustic nerves are not paralysed, it is possible to make the sound waves appreciable through the medium of the teeth or the cranial bones.

Towards the end of 1879, Mr. Rhodes, of Chicago, took out a patent for an apparatus called an Audiphone, the remarkable efficacy of which was proved by many experiments. Some experiments undertaken in deaf and dumb institutions showed the possibility of making promptly audible musical sounds, and even the articulation of the voice; hence rendering rapid instruction possible. Such an instrument would of course *a fortiori* be still more useful to those partially deaf.

Rhode's instrument, made of hard rubber, was in the shape of a triangular fire screen, kept in a state of semi-flexion by a thread fastened to the handle.

The apparatus is about 24 centimetres wide and 30 long. The deaf person holds the handle and places the opposite extremity between his teeth, with convex surface outwards.

Dr. Colladon, of Geneva, (*a*) wishing to make the instrument attainable even by the poorest, used, in place of hard rubber, a plate of smooth pasteboard, or "carton d'orties." These pasteboards, says the author, are tenacious, compact, homogeneous, and elastic; they are also very supple, if not more than one millimetre in thickness. Slight pressure of the hand holding a disc cut from one of these sheets of pasteboard, whilst its upper extremity is arched against the teeth of the upper jaw, is sufficient to give a convenient curve variable at pleasure, without fatiguing the hand or the teeth.

"Among other experiments at which deaf mutes assisted." writes M. Colladon, "I would cite one which took place on January 14 in the presence of several persons. We first ascertained those who could only hear the sound of a grand piano very near, and then determined the distance at which they ceased to be affected without using acoustic instruments. Some felt the vibrations only by movements of the parquet covered with carpet. When they were furnished with audiphones they all showed that the sensation of sound was distinctly transmitted to the head, sometimes on one side and sometimes on the other, according to the individual." M. Colladon cites many examples, truly marvellous, among others that of a young lady, formerly an artist, a very good musician, who had become completely deaf, but who showed excessive joy when, by using the audiphone, she was able for the first time for fifteen years to hear airs on a piano.

After reading all this we became impatient to verify the exactitude of such good results. The apparatus of Rhodes and Colladon were supplied by M. Trouvé, the ingenious and skilful maker of magneto-electric instruments. Experiments were made at the National Deaf and Dumb Institution in the presence of Drs. Hermet, Moure, and Jacquemart, M. Trouvé, and many who attended my clinique. We chose a certain number of deaf mutes easily reading the lip language, speaking very correctly, very intelligent, having preserved the possibility of hearing the voice, but unable to distinguish words by the ear. The eyes being closed, they were never able to comprehend a single word spoken, even in a loud voice, against the audiphone.

Giving up the deaf mutes, we continued our experiments on patients. We chose those who had some difficulty in distinguishing speech at a certain distance; all declare that they experienced with the aid of the audiphone no great difference in the way in which they heard.

I have tried the audiphone in my practice, amongst other cases in that of a young lady who seemed in particularly favourable conditions. She was affected with anchylosis of the ossicular chain, and could only hear speech with the assistance of a hearing-tube, or when one spoke into her ear. I was able only to make myself heard when speaking to her at 5 or 6 centimetres distance from the audiphone, and a little below the middle of the instrument; without the help of the instrument, and at the same distance she could not hear me. For her the instrument had some value, but it was only relative, since it was necessary to speak in the most inconvenient manner, two persons could not be heard at once, and the piano was only heard at a few centimetres distance.

How can we explain the differences between M. Colladon's experiments and mine, unless we think that the author has been deceived, and that lip-reading has sometimes supplied the deficiencies of the instrument.

It only remains to study the telephone and its utility in deafness.

Bell's telephone which, by electricity, transmits sounds to a great distance, is of no advantage to the deaf. If, indeed, the distance is left out, the intensity of the sound is not increased, and perception by weakened or malformed organs is impossible. The telephone which transmits the sound-waves by increasing them, is the instrument called the thread-telephone which, up to the present time, has only been an infant's toy, or an instrument employed only for demonstration in the chamber of the physicist. M. Trouvé conceived the idea of making an acoustic instrument of it, and although we have together made researches on the best applications we can make of it, I do not hesitate to publish, prematurely perhaps, the object of our researches.

The telephone is composed of vibrating plates, to the centre of which is attached a thread of hemp or metal, which, when it is very tense, transmits the sound-waves to a great distance, and with mathematical precision. This apparatus may be used by the deaf in two ways. If the strengthened sound-waves can enter by the external meatus it may be used like an ordinary ear-trumpet. If the sound-waves cannot be transmitted through the middle ear the vibrating-plate of the receiver is replaced by a piece of wood to which the thread of the telephone is fastened by a small iron hook. This piece of wood is held between the teeth of the deaf person. The sound-waves are transmitted by the hempen thread with great exactitude and great intensity. What facilitates the hearing of the semi-deaf person is the prolongation, so to speak, of the sound-wave which allows the organ to appreciate the sensation which it experiences.

If the hempen thread be replaced by one of metal, the intensity of the sound is increased tenfold, and the impression becomes painful by its exaggeration. The inconvenience of the iron thread is, that it alters the tone-quality (timbre) of the sound, rendering it metallic and very disagreeable. Another inconvenience is, the necessity of always having the thread tense between the vibrating extremities. This condi-

(*a*) *Nature*, Jan. 14, 1880.

tion makes a portable apparatus of little use. The telephone, therefore, must be especially a fixed apparatus. The thread may follow the shape of a wall, provided there is a vibrating plate wherever there is an angle.

The telephone does not require one to speak against the surface of the vibrating lamina. A sufficiently large apparatus—the head of a drum, for instance, might be placed in front of, or above, the head of an orator and allow the propagation of the sounds in all parts of the enclosure in which he speaks.

We may conceive numerous applications which might be made of this apparatus. In schools half-deaf children could be admitted into the ordinary classes from which their infirmity now excludes them. In political assemblies certain parts might receive the telephonic threads and allow the speaker in the tribune to be heard. In theatres certain boxes might be specially furnished for the deaf, and the isolation in which their infirmity places them would be considerably lessened, since they would be able to take part in public life.

These are yet but hypotheses and hopes, but theory justifies them, and we count upon their early realisation.

Department of Lunacy.

"MEDICAL PRESS AND CIRCULAR" SPECIAL COMMISSIONER'S REPORT ON PRIVATE LUNATIC ASYLUMS.—II.

THE arrangements for securing the safety of lunatics, and of the public to which they are a source of danger, might be in some particulars altered with advantage. In so far, however, as the plan in vogue of certifying insanity is made use of to convey patients to private asylums, there is absolutely no reason to regard it as inefficient, or as favouring improper practices. The certificates are not at the command of proprietors, and these latter are, under the severest penalties, required to demand the most absolute proof of certification in a proper manner, ere venturing to receive any new inmate. Not a few statements have been made to the effect that individuals have been, and are even now, occasionally incarcerated on the requisition of some interested person, who, by bribery, has been able to purchase the acquiescence of an asylum keeper in an unjust imprisonment. Those who are given to spreading such false statements do not reflect on the harm they are guilty of doing, nor do they stop to think how utterly untrue they must be. Every asylum is licensed for a definite number of inmates, beyond which none can be received. Each patient's arrival is at once entered, and news of it forwarded to the Lunacy Commissioners, and to the local magisterial authority. These, one or other, or both, visiting the establishment unannounced, unexpected, carefully inquire into the history of, and examine, the fresh arrival, and any flaw in the method of committal must, on the spot, result in the discomfiture of the one attempting the fraud. It may possibly happen that a patient is unnecessarily certified; that is, may be described as of unsound mind, while in reality suffering from nothing more serious than a passing aberration. In this state anxious friends, and physicians called to examine the case, may possibly agree that temporary seclusion in a licensed establishment would be desirable; and it may happen that on arrival at the institution selected, the patient has recovered his mental balance. This, I was informed at two places, viz., Stretton House, and Haydock Lodge, had occurred shortly before my visits, and the patients were as quickly as possible returned to their friends. It may be well for a moment to consider the influence of public and private asylums in these particular cases. A patient properly committed arrives at the prison-like abode in which the county locates its mad, and at the very outset receives a shock of itself sufficient to affect a recently restored balance. Forthwith, ere it is possible any evidence can have been elicited to prove the case is not one of the ordinary kind, the unfortunate patient is hurried into association with a horde of lunatics, and being at once left with no sane being near other than the salaried attendants, what else than despair will be engendered, and a feeling of utter despondency induced by the rigid officialism everywhere exhibited? The mind but recently recovered from its disturbed state is placed under the least favourable conditions for maintaining the improvement effected; and there can be but little doubt the prison-like atmosphere of public asylums has in numberless instances, converted a merely temporary brain disease into a chronic madness. Search diligently as one may, there will never be found records of "discharged on admission" from the Government institutions, such as are among the documents of private asylums, the cause being sufficiently evident. On reaching the private retreat, the dazed, tired traveller is received with expressions of kindness and sympathy in place of the routine utterances of officialism; he feels he is amongst friends who are interested in him, and the home-like surroundings serve to strengthen his confidence in the place to which he has been brought. If, haply for him, his condition is that of one whose insanity has gone from him, the fact is very quickly made apparent, and the existence of the patient, pending the formalities preceding his removal, is one of pleasant association with the family, in which he is received as a guest. Under the one system every inducement is held out to preserve the regained balance, every aid is rendered to the same end; under the other no special heed is taken, but a dull, machine-like routine is maintained, under which it is left a matter of chance whether the patient progresses or recedes.

Nothing less than the wide-spread ignorance of the people on all points relating to asylum management could admit of the erroneous ideas on the subject of committal to one of these places. It should be remembered, however, that these misconceptions have been persistently fostered by sensational writers, and by authors who have chosen to make capital out of depicting scenes that have no existence in the present. "Hard Cash" was written of a time that was before the benevolent efforts of Lord Shaftesbury; and the novelists who have followed in the steps of Charles Reade, instead of improving as the system he denounced has been abolished, have continued to reproduce, with the servility of imitators, descriptions which the original author would hasten to correct. Every attempt ought to be made to remedy the great evil being done to the character of institutions to which society owes much of its comfort; and among the earliest impressions it is wise to instil, is that of the absolute inability of any asylum superintendent, of his own accord, to decide the fate of a lunatic.

When the certificate on which the patient has been removed, is presented, and its accuracy established, then, and not till then, does the authority of the keeper commence. In the instances where this authority is that of a paid deputy, it must be apparent that his only interest is to duly perform the task he is paid to execute. It is nothing to him that a case is more or less sane on admission; for him to inquire fully into it would require an amount of time and trouble, which no salaried officer, as a rule, will care to expend. In the private asylum, however, it is very different. It has been ungenerously asserted that patients are detained at these places even when no necessity for the proceeding exists. In my experience the very reverse is the case.

Undue willingness even is shown to discharge the unfortunate subjects of disease, so that it does not unfrequently happen that the same patient is within a very short period returned as a relapse. There are two incentives to this. In the first place a large percentage of "discharged cured" ensures a high reputation to the institution, and a certainty of its being held in favour. In the second, the natural instincts and kindness of *interested* attendants ensure that a patient able to enjoy the home association with personal friends and relatives, shall as speedily as possible be sent where these are of the most perfect kind.

It needs only a slight acquaintance with the great majority of private proprietors to be assured these feelings *have* a weight with them; and the more certainly since they know by experience the benefits to themselves and their charges thereby accruing. I had the pleasure to stay more than a week at one institution; during this time two patients were admitted, and I was struck by the excessive minuteness of the observances in connection with their entry. The utmost confidence is to be placed in the regulations as they have to do with the asylum proprietors. How far the actual certification can be amended is another matter altogether. I am concerned only with the admission, here, of such as *are* duly certified; and there is on this head no possibility of an undue influence being exerted by the proprietor.

THE BARONY PAROCHIAL ASYLUM.

The Barony Parochial Asylum at Wodilee in the neighbourhood of Glasgow, may perhaps afford some indication of the economy which may be expected should the management of the pauper insane in England be taken out of the hands of the magistrates and placed in the hands of boards of guardians, or of committees of county boards with guardians as a predominating element. It has been erected by a parochial board—the Scotch equivalent of a board of guardians, and is the most costly and sumptuous asylum in Scotland—while the rate of maintenance of its inmates does not betoken parsimony in its domestic affairs. It was unfortunately the scene of a fire, which destroyed its west tower on the 16th of October last. It is very creditable to the management, as the visiting commissioner remarks that even, when the fire was at its height the wants of the patients received their customary attention, and perfect tranquillity was maintained. No confusion occurred, and neither patient nor attendant received any injury. The importance of having a trained and properly exercised fire brigade was made very apparent. By their exertions the spreading of the fire was prevented.

The annual death-rate from the seven principal zymotic diseases averaged 7·9 per 1,000 in the principal large towns, and ranged from 2·9 and 3·9 in Bristol and Brighton, to 15·0 and 24·1 in Hull and Leicester. Scarlet fever showed the largest proportional fatality in Oldham and Leicester. Three deaths were referred to diphtheria in Birmingham. Small-pox caused 4 more deaths in London, 5 in Dublin, but not one in any of the other large provincial towns. The deaths referred to diarrhœa in these towns, which had steadily increased in the nine preceding weeks from 51 to 807, further rose last week to 864, and were equal to an annual rate of 6·0 per 1000.

REGISTERED FOR TRANSMISSION ABROAD.

WEDNESDAY, SEPTEMBER 1, 1880.

DR. ORME DUDFIELD'S "ANNUAL REPORT."

The Annual Report on the health, sanitary condition, and other matters connected with the parish of St. Mary Abbotts, Kensington, by Dr. T. Orme Dudfield, Medical Officer of Health, has just been issued. We have before drawn attention to the admirable manner in which Dr. Dudfield's reports are presented, and the present one is in every respect worthy of receiving the highest commendation as a painstaking, laborious, and careful epitome of the medical history of the district over which he exercises an official control. Many points dealt with in this Report are of striking interest, and while it details the actual sanitary condition of Kensington, it is, in places, pregnant with suggestions for the better administration of the district comprised within the account. The parish of St. Mary Abbotts increased in population in 1879 to the number of 2,650 over that of 1878, but it is satisfactory to find the death-rate below the average, though higher than that for 1877, which, as will be remembered, was exceptionally low. The number of new houses rated in 1879 exceeded 700, and it is much to the credit of the sanitary arrangement connected with so large an increase in the number of habitations, that the mortality of a rapidly

spreading district is kept within the limit mentioned. In a new neighbourhood there are always to be contended against, evils of a kind that do not affect an old established parish, where fresh buildings are few and far between; and in the parish under Dr. Orme Dudfield's care exceptional disadvantages exist to favour the prevalence of a high death-rate, in the absence of that rigid supervision which it is the duty of a medical officer of health to exercise. We learn that "there are miles of streets of houses inhabited by a class of persons who, in the older parts of the metropolis, would find shelter in dwellings that, by comparison, might be termed squalid. But rents are high, and high rents mean over-crowding, which is sure in the long run to raise the death-rate wherever it exists; and, indeed, there is reason to believe that it has already led to a greater variation in the rate of mortality in different sections of the parish than ought to prevail." The zymotic diseases, the deadly scourge of unsanitary districts, gave rise to a number of deaths below the average; whooping-cough, diarrhœa, scarlet fever, and measles being those diseases to which the higher rates are attributed. The mortality, however, from all the several zymotic diseases, excepting diphtheria and whooping-cough, has been below the average, a circumstance on which justifiable satisfaction is expressed. The manner in which disease may become epidemic is well illustrated in this Report, Dr. Dudfield having been at particular pains to show the culpable way in which persons suffering from infectious complaints are permitted to come into contact with others susceptible of receiving the taint. On this subject he very pertinently remarks, "if we would trace all outbreaks to their origin, such a case would be made out as would fairly startle the public mind, and help to get rid of the too common notion that infectious diseases being 'in the air,' it is useless to take precautions against the spread of them, the fact being that the 'area of infection' is very limited, the victims having been brought within that area sometimes through sheer wilfulness, sometimes through indifference, and sometimes through ignorance. Now and then the conveyance of infection is effected by the 'sick' person himself, who, being allowed to mix with healthy but susceptible individuals—mostly children—becomes a migratory centre from which disease spreads, and there can be little doubt that in the circumstances of our poor, living as they do in crowded and un-ventilated rooms, clothing, *e.g.*, of parents and unaffected children, exposed by day and night to infection, become a means of spreading disease in schools, workshops, &c." This conclusion is little liable to refutation, and is more than borne out by the details presented in the volume, and it is a matter to which serious attention ought to be directed, because of the very important influence it must exert over the spread of infectious complaints. Many objections are urged against the present system of parochial assistance in fever cases, a system to the disadvantage and circumlocution of which a goodly number of deaths can be attributed. Not only does it in a measure favour the designs of those who seek to keep infectious cases under home treatment, but in many ways it affords means for the evasion of rules of removal, &c., that should be rigidly enforced in every instance of fever or other dangerous illness. The regulation requiring the vestry of a parish to pay for the continuous maintenance of the number of beds considered necessary for its needs in a special fever or small-pox hospital, if it would retain the privilege of sending patients to it for treatment, is, says Dr. Orme Dudfield, not unreasonably objected to, seeing that during considerable periods there might be no occasion for them. The report then explains "the only perfectly satisfactory mode of dealing with the question would be to spread the burden of infectious diseases over the whole metropolis, or a 'common fund,' and to give free admission to all sick persons desirous of being isolated in the hospitals, or who may be sent to them for isolation (excepting only such persons as may be able to pay for medical treatment, &c., and these should go to the London Fever Hospital, or the London Small-Pox Hospital)." This suggestion has been made before by the same authority, and there seems good reason why it should be fully discussed as a means of settling a vexed question.

There are many other matters of great interest dealt with in Dr. Dudfield's report, to which, if practicable, we shall turn again at an early date.

THE LITTLE SUCCESS OF SANITATION, AND WHY?

At the meeting of the British Medical Association in 1879 Dr. Fergus asked the question, What influence had *sanitation* during the past forty years exerted in decreasing the rate of mortality in the home population? He answered thus: "During these forty years large sums of money have been expended in sanitary improvements." Yet, "discarding individual years in which there had been fluctuations in both directions from various causes, it happens that in each of the three decennial periods, 1841—50, 1851—60, and 1861—70, the rate of mortality has been identical—namely, 22·35 per 1,000." With reference to the above, the deduction appears reasonable, either that "sanitation" has yet to be applied in the particular direction in which its influence will tell in the most definite manner; or else, that conditions are at work, the effect of which is to a great extent to neutralise the results that otherwise would accrue from the application of the principles of preventive medicine. He adds: "The first facts that strike us is the increase in the diarrhœal group of diseases, the addition of a new zymotic—namely, diphtheria—which does not appear till 1851, and *the small diminution of typhoid* in the fever group." It would seem evident from these remarks that the desire of the lecturer was not to depreciate the value of cleanliness and good conservancy, but to bring into *relief* the too great tendency of the time, to consider them, and neglect a variety of other conditions affecting individuals and masses.

Some of the conditions which have so far neutralised the best devised measures of *sanitation* are thus enumerated in the *Contemporary Review* for August, 1880. In Ireland there are 227,000 families living in mud cabins of a single room. "Are there not in our great cities other 227,000 families living in cellars and single rooms, in worse air, and in worse surroundings, and in worse contamination, both in mind in body, in close contiguity

to gin palaces, and other incentives to vice? And we should not be far wrong if we doubled, or even trebled, these 227,000 for the whole of Great Britain." In rural England the state of things appears to be equally bad; the majority of cottages in rural parishes are deficient in almost every requisite "of health." Physically, a ruinous, ill-drained cottage generates any amount of disease, fevers of every type, catarrh, rheumatism, and intensifies to the utmost the tendency to scrofula and phthisis, which, from their present inter-marriages and their low diet, abound so largely among the poor. Here is a description of such a cottage: "An agricultural labourer's family occupying a single room; there were thirteen children; four occupied one bed, two lying at its head and two at its feet; two slept under this bed; an infant was in a cradle—a kind of box fastened on the window-sill; the rest were about the floor." In our cities things are equally bad; families living, and sickening, in foul rooms of nine, or at most ten feet, square; the only society for the men and women, the public house; drunkenness, brutality, and degradation such as to demoralise their victims until they become an opprobrium to our civilisation. Are these not in such conditions sufficient to account for the ill-success that has hitherto attended mere measures of sanitation? It is not alone to the *water*, the *milk*, used by persons under such circumstances that we should look for the causes of disease among them; but it is to the ulterior circumstances under which they are, in a manner, *forced* to occupy such places, and to lead such an existence as they do.

THE INDIAN TROOP SHIPS.

Is it really the case that the "authorities" contemplate the "reorganisation" of the Indian troop service? According to rumour some such change is actually entertained. Perhaps the one grain of truth in it is contained in the contemplated adoption of Kurachee as a post for its purpose instead of Bombay; and if this be so, convenience and economy would no doubt be alike consulted, in so far as the transport is concerned, of our troops proceeding to and from the Punjab and Northern India generally. Perhaps it is that a change in the present undoubtedly costly system of moving our soldiers and their families has come to be considered from a financial or other point of view.

It would appear that the *idea* of having a distinct line of Indian troop vessels was adopted from the success with which similar ships belonging to the French navy conveyed troops to and from China during the expedition of 1860-1. Besides the military reasons, with which, in these pages, we have no concern, the introduction of a line of vessels somewhat after the model adopted by our allies, was advocated on medical grounds. It was thought that, instead of sending invalids in great numbers to hill stations, where comparatively few recovered sufficiently to be of any subsequent real use as soldiers, they would by these ships be speedily transported to their native climate, and so obtain an increased chance of recovering their health; at the same time that the service itself would benefit by the restoration of *old* soldiers to the ranks. This reasoning has been a good deal affected by changes of system introduced into the army since the Indian troop service was matured: nevertheless its soundness at the time is confirmed by statistics then adduced. As illustrations of what actually happened per thousand invalids sent to the hills in those days, the stations of that nature in the Bengal Presidency were taken with the results that at Darjeeling 50·63 died, and 139·24 had subsequently to be sent to England; Nynee Tal, 21·73 and 118·47; Landour, 147·05 and 147·05; Kussowlie, 35·14 and 55·08; and Murree, 29·26 and 229·26 respectively. The recommendation was therefore natural that such stations should rather be utilised by sending to them young and newly arrived soldiers of whose health the cool climate of such elevated regions might be expected to be preservative, the sickly and weakly being shipped for home as freely as circumstances would permit, the railways and tramways, such as they then were in India, being used as means of speedy transit to ports of embarkation. With the near prospect in view of the Suez Canal being completed, the relative advantages to health of the "overland" route, and that round the Cape was considered in their medical bearings, the result being that taking a crowded ship by either route, the advantage seemed to rest on the side of a speedy return to England, rather than with all the advantages of a long sea voyage, *plus* its monotony and chances of severe weather, and its attendant discomforts. Rightly or wrongly, it was at the time thought that with the increased comforts and other advantages to be obtained on board the proposed troop ships, and by the intended arrangements connected with them, no particular harm need be looked for from transit through the Red Sea and arrival in England, irrespective of season. Suffice it to observe, however, that the views on these points now entertained differ materially from those of fifteen years ago; that in fact one of the greatest drawbacks against the system now in force is that of landing men, women, and children in the dead of winter in this country direct from the great heat of India, the condition of body often ill suited to withstand the effects of such sudden change—the clothing, more especially as regards soldiers' wives and children, by no means such as were required to protect the person from cold.

Certain forms of illness were specially named in medical reports on the contemplated new system as likely to be aggravated by the return of their subjects to England during the severity of the winter season, namely, chest affections, rheumatism, and constitutional syphilis. But then, it was argued, persons affected with either of these diseases seldom, if ever, again become efficient soldiers; hence probably their individual requirements in a purely professional, and from a "service," point of view, were not necessarily in accord. As, however, in the event of the changes being really contemplated in the method of sending troops to India and bringing them home again, it seems desirable in the interests of them and their families, that these and some other matters here touched upon, be taken into consideration by "the powers that be."

In so far as the troops themselves and their belongings were concerned, personal comfort was secured on board the magnificent contract ships by which, prior to 1867, troops were conveyed to and from India, to a degree beyond what from the nature of things is attainable on board the troop ships by which since that date this service has been

performed. No doubt also the competition between shipping interests resulted in our troops being transported at the smallest possible cost, except as regards the one item of "fittings," and these had to be put up in each successive vessel engaged, to be of no further use than the one voyage—outward or homeward, as the case might be. The circumstance, however, of England being dependent upon private enterprise for the conveyance of her troops to and from her greatest dependency, was looked upon as no longer advisable, and no doubt the occurrences of the Indian Mutiny in 1857 hastened this decision. The fact of numbers of disused, but seaworthy and good ships lying useless in our dockyards, and of naval officers on half-pay being anxious for employment, further indicated the readiness with which ships could be fitted out in every respect for the transport of troops; but the idea never entered the minds of the chief advocates of this plan that the vessels in question were to be on the establishment as regular men-of-war, or, indeed, anything else than what was indicated by their very purpose, namely, that they should be *floating barracks and hospitals;* nothing more, and nothing less.

Notes on Current Topics.

The Convalescent Home for Dublin.

THE small-pox epidemic in Dublin which now, happily, shows signs of dying out, has brought again to the front the effort to establish a convalescent home for the city which, a couple of years since, was ineffectually made. At that time a sum of money was subscribed by the public which now lies at interest, but the amount was utterly inadequate to provide, much less to endow, such an institution, and the Dublin Corporation did not see their way to undertake the responsibility of the establishment. In July last the Organising Committee adopted and forwarded to the Public Health Committee of the Corporation resolutions which asked the civic body what annual sum they would contribute, or whether they would consent to pay a capitation for each patient admitted from the city to the home.

In reply the Public Health Committee adopted the following curious resolutions—

"1. That any Convalescent Home for the reception of patients recovering from infectious diseases should be attached to Cork-street Hospital, and constitute a department of that institution. 2. That the amount already contributed towards the erection of a Convalescent Home should be handed over for that purpose by the Mansion House Committee to the governors of Cork-street Hospital. 3. That when such Convalescent Home shall have been provided, the Council be recommended to contribute towards its maintenance, by way of a liberal capitation grant for the support of such patients as may have been admitted to the fever hospital from the city; the support of patients admitted to it from the suburban districts being necessarily defrayed by their respective local authorities."

The *prima facie* sense of the resolutions is, that the Public Health Committee will recommend the Council to pay for the city convalescents on condition

a. That the citizens provide the establishment without any help whatever from the civic sanitary authority;

b. That the money already subscribed be handed over to the managers of a single fever hospital;

c. That the Home in which the patients are to convalesce shall be "attached" to the Fever Hospital which is at the moment reeking with epidemic infectious disease.

The Public Health Committee does not say whether or not "attached" means "adjacent," and we can hardly believe that it is seriously proposed to build a convalescent (!) Home within the precincts of a city fever hospital. But, in any case, the reception of the proposal by the Public Health Committee is decidedly not encouraging to those who are striving to do the work which the Committee itself ought to have done long ago.

Unwise Lingering.

THE manner in which our legislators are lingering over the patchwork proceedings to which the failing energies of fagged-out members are at present being devoted, is a melancholy exhibition of that unwise spirit characteristic of the multitudes who, through ignorance or carelessness, neglect the dictates of nature. If they have worked honestly and well, the members of the two houses of Parliament have earned and require a holiday from labour. But the past week will probably have contained incidents enough to prove that earnest or good performances are a long way from the minds of those who constitute, at least, one assembly of the body politic. From the point of view, either of expediency or of health, there was nothing but miserable show of obstinate perversion contained in the prolonged sitting of Thursday and Friday. If the House of Commons desires to effect anything that will be of advantage to the country, ere its sittings are adjourned, it will best achieve its purpose by exercising a wise discretion in the choice of its business hours. Sleepy legislators, and yawning partisans, are little likely to aid on any measure of advantage, or to be in a position to submit the propositions laid before them to a critical analysis that can be possible only to calm judgments and well-rested minds. The commendable course is for the House to dismiss its present purpose, and seek immediately the change and repose it so urgently requires, by adjourning at once to sea and moor.

Worked to Death.

A CURIOUS case of death through overwork was investigated at the Coroner's Court in Sheffield last week. An iron worker suddenly fell down dead after labouring continually from Thursday morning until Friday afternoon, the sustained effort having been made at the demand of the master, who desired to complete an order with all despatch. The verdict returned by the jury at the inquest recorded death from exhaustion, caused by overwork, but there is no evidence to show the condition of the heart or other organs. The case would be one of great interest to have in detailed account, but nothing can detract from the serious nature of such slave-driving as this unfortunate man has been subjected to. There is reason to fear that Sheffield is not the only scene of such accidents.

Inquest Episodes in Belfast.

THE Belfast Borough Coroner who, it may be necessary to premise, is a medical man, has been distinguishing himself, and, if we may accept the reports of his proceedings in the Belfast papers as correct, has been contributing a considerable quota to the contempt in which coroner's courts are usually held. We find it narrated in the *Belfast Morning News* of August 14, that a boy was kicked on the leg by a man, fell ill, and died, and the medical man deposed that death was caused by inflammation of the periosteum. The lad was kicked on the 31st of July and died on the 12th of August. He was professionally attended by Dr. Graham, Dr. Browne being finally called in for consultation. The verdict of the jury was of the usual comical character, namely, that the deceased came to his death by injuries. The Coroner directed that Dr. Browne should be summoned to give evidence, and not Dr. Graham. Dr. Browne attended, informed the Coroner that the case was not his, but Dr. Graham's, and declined to interfere. Then, and then only, the Coroner sent a summons to Dr. Graham, who informed the messenger that if he had been summoned in regular course he could have attended, but that he could not do so then, having an engagement for seven o'clock. The messenger duly informed the Coroner, who told the constable to take a fellow-constable with him, and bring Dr. Graham to the court. The constable very prudently asked for written authority for so high-handed a step, and the Coroner was about to make out a warrant when it was announced that Dr. Graham was at hand.

The Coroner—You are here now, and had better remain. Dr. Graham—You can issue your warrant. The Coroner—And I'll do it. Dr. Graham—I will abide the consequences. The Coroner—Well, we will take your evidence very shortly. Dr. Graham—It is now ten minutes to seven, and if you say I will not be kept more than ten minutes I will stop. The Coroner said he could make no such promise. Dr. Graham—It is all your own fault. The Coroner said he must stop. He had been duly summoned. Dr. Graham (emphatically)—It is disgraceful. The Coroner—Put that man under arrest, and retain him under arrest. Constable Welsh then took Dr. Graham into custody. Dr. Graham—Now, have I been fairly treated in this matter? The Coroner—Dr. Graham, I want no altercation. You are to give your evidence. You are now in custody, and will be until I give an order for your release. Dr. Graham—I really have an engagement at seven o'clock that I must attend to. The Coroner—I am not disputing that, but this is your first engagement. Dr. Graham—Am I under arrest. The Coroner—You are. Constable, will you come here and give the doctor the book. Constable Welsh having hand the book to Dr. Graham, the Coroner said—You are going to be sworn as a witness, and your position is now that of a witness. Dr. Graham—Am I under arrest? The Coroner—You are not at present, if you please, to take the book. Dr. Graham—I am under arrest? The Coroner—Take the book. Dr. Graham—I am under arrest now. Don't you say I am in custody? The Coroner—Take you that book. Dr. Graham (with emphasis)—Am I under arrest? The Coroner—Come forward and take the book.

The *Belfast Morning News* asks what the medical profession will think of this, and we feel it necessary to say that the transaction was most unseemly, and, in all its aspects, discreditable to the Coroner. That officer is empowered by the Act to summon any duly qualified practitioner "in actual practice at or near the place," and he, therefore, did not act illegally in calling for Dr. Browne, though he plainly infringed the spirit of the law, which is, that the medical man who had best knowledge of the cause of death should be called as a witness. Then again, the Coroner has a right to summons his witnesses for any time and place he pleases, but he is both legally and morally bound to name such time and place as the witnesses may reasonably attend, and, by giving Dr. Graham an hour's notice, he did not fulfil this obligation. Lastly, the scene above reported displayed ill-temper, which was to be regretted in each case, but was altogether indefensible in the judge of the Court. We doubt that the Coroner had any power to arrest Dr. Graham under the circumstances reported, and we do not believe that he has any right to compel witness to swear by such means. So much for our legal view of the Coroner's conduct. From a professional point of view, the squabble in open court was, we think, very discreditable, and we hope that the Coroner will benefit by the publicity which he has achieved, and learn in future to treat his medical witnesses as gentlemen should be treated by a gentleman.

Association Meetings.

Two important associations will hold their annual meetings within the next few weeks, both at Edinburgh, and both in a sense associated with medical science. The Library Association of the United Kingdom is a useful society which unobtrusively, but certainly, is doing valuable work in the way of library classification and improvement, and its influence is being felt even by those in charge of medical libraries. Though but four years old, it has accomplished much useful work, and we learn that it is in contemplation to invite aid in a special attempt to associate within one descriptive guide an account of all the important libraries of medical and allied societies in the Kingdom. This would be of inestimable service to the great multitude of hard-worked professional men who devote their attention to extending the literature of their calling, and deserves the warm support of everyone interested in the profession. The other body is the Social Science Association, the President for 1880 being Lord Reay. Dr. John Beddoe, F.R.S., will preside over the "Health" section, and there is good reason to anticipate that the Edinburgh meeting will be in no wise less interesting or less fruitful than that held at Manchester in 1879.

Butterine.

THE Corporation of Dublin recovered penalties last week from a number of provision dealers for selling butterine as butter. They were fined £2 each, and were informed that repetitions of the offence would make them liable to a fine of £20.

We believe that the sale of butterine, under the name of butter, in the United Kingdom is simply enormous. Travelling in Holland recently we saw two large manufactories of it, and the steamer which conveyed us to English shores brought an exceptionally small consignment of 800 barrels of the stuff. We should, indeed, be well pleased to see it largely introduced into consumption as a cheap and good element in the people's food, but we are equally glad to see that the Dublin Corporation is engaged in the prosecution of rogues who palm it off on the public as butter.

Iodoform in Chronic Otorrhœa.

AMERICAN physicians have advised the use of iodoform in otorrhœa (*La France Médicale*). Czarda has tried it with success in the otiatric clinic of Professor Zanfal, of Prague, and given his results in the *Weiner Mediz. Presse*. He has used it in twenty-one patients of ages varying from four to thirty-three years. Most of them had suffered for months—some for years. The otorrhœa was consecutive to scarlatina, measles, typhus, &c. In most of the cases the membrana tympani was more or less completely destroyed; in the others it was perforated. The mucous membrane of the aerial passages was swollen and red. The secretion was very abundant in many cases; in five of eighteen patients both ears were affected. In eight cases instillations of a solution of nitrate of silver had been used for months; in two patients recourse had been had to powdered alum.

The iodoform is used thus:—After the ears have been thoroughly cleansed, a quantity of powdered iodoform, at first moderate, is blown in; later, when the suppuration has diminished and there is marked amelioration, there is introduced into the tympanum cavity a plug of cotton wool imbued with iodoform.

The insufflated powder or the plug of cotton wool is left in its place for three or four days; each time it is renewed the ear is carefully cleansed. The suppuration diminishes rapidly from the first application of the remedy. The pus has no fetid odour, even after a prolonged presence of the iodoformed plug. Cure generally takes place in from one to four weeks. The mucous membrane of the auditory passages gradually resumes its normal character.

The iodoform acts as a disinfectant, a resolvent, and a protective. It has besides the advantage of not forming with the pus fetid concretions, as is the case with alum. The odour of iodoform is easily covered by the addition of camphor, ethereal oil of bitter almonds, tannin, or a few drops of essence of peppermint or of fennel.

The Constant Current in Intestinal Occlusion.

DR. BOUDET reports two successful cases in the *Progrès Médical*. The first patient was suddenly attacked with strangulation of the small intestine from peritoneal bands or adhesions, shortly after recovery from an acute peritonitis; the recent date of the latter prohibited any attempt at surgical interference. In the second case there was such obstinate obstruction with intestinal paralysis from fæcal accumulation in the cæcum and sigmoid flexure, that all ordinary treatment failing operative measures were contemplated. In both cases the constant current from a Gaiffe's peroxide of manganese battery of 6 increased to 10 or 14 cells was used, the poles being applied either abdominally, or recto-abdominally (the negative attached to a female catheter in the rectum, and three rheophores from the positive pole on the abdomen). The applications, 10 in the first and 8 in the second case, varied in duration from half-an-hour to an hour or an hour and a-half each, but were not made continuously, Contact was established about every half minute and over, during a second—each closure of the current produced a violent intestinal contraction, and the sound placed in the rectum showed well these contractions by its in and out movements—several times the induced, instead of the constant, current was tried, but it provoked intolerable pain and seemed to act only on the muscles of the parieties. It caused no intestinal contractions or rumblings, or movements of the rectal sound. He uses the induced current only for exciting the muscles of the abdominal walls whose contractions are often very valuable in aiding those of the intestine. With proper precautions there need be no risk of eschars from the constant current. A hollow rectal sound is advisable in order to allow fluid and gaseous matters to escape through it. It is necessary to repeat the application much oftener than is indicated in special treatises, and to prolong them according to the state of the intestine. In one case there was sudden strangulation by peritoneal bands or adhesions, the intestine preserving all its contractility, strong excitations augmented its contractions and detached it from its adhesions. In the other case the electrical current gradually restored to the intestine its energy, and after each application it emptied itself partially of its contents, but four days elapsed before obtaining a complete result.

Lunacy in Ireland.

LOOKING to the conditions of lunacy in Ireland in a comparative point of view, the inspectors of Irish asylums remark that, as regards the years 1878 and 1879, very little difference is noticeable.

On the 1st January, 1879, there was, as already enumerated, a total of 8,407 patients in district asylums. During the year 2,392 were admitted between both sexes, of whom 1,955 were cases of first attack, and 438 relapses—the comparatively large number of the latter indicating a marked difference between the liability of a recurrence of diseases in mental and physical affections. As regards the aggregate of 10,800, 1,004 were sent out recovered, being at the rate of 42 on admissions, and not quite 10 on the whole number under treatment.

The deaths, of which two were accidental, and one from suicide, amounted to 949, constituting a percentage of mortality of $8\frac{3}{4}$ on the entire number in asylums, or nearly one more than in 1878—an excess which can be very fairly accounted for by the unprecedented harshness of the season, and with it the prevalence of bronchial diseases. Hitherto deaths in Irish asylums have been, as a rule, below par.

To get Leeches to Fasten.

ALMOST every physician has at times experienced the difficulty of getting these animals to bite. The following plan is commended, and will be found effectual in all cases when the leeches are healthy. Put the animals in a small glass vessel half filled with water. The part of the body which is to receive them is carefully washed with warm water, and the glass is quickly inverted upon the skin. The leeches attach themselves with surprising rapidity. When all the animals have bitten, the glass is carefully removed, the water escaping being absorbed by a sponge. If a single leech is to be applied, the same plan is adopted, using a test-tube in place of a glass; by this means the animal may be compelled to bite at just the point desired.

Anti-Vaccinators' Penalties.

A RETURN has been presented to the House of Commons, showing that up to March last 3,888 persons in England had been fined, and 87 imprisoned for non-compliance with the requirements of the Vaccination Acts. Of the latter 73 were sentenced to periods exceeding a fortnight, but less than a month. In three cases only has the same person been imprisoned twice, and no one person more than twice. In numerous cases, however, fines have been repeatedly imposed on the same person; one in Lancashire has been fined twenty-one times, the total amount paid having been £25 17s.; and one offender in Berkshire has appeared before the court twenty-five times, but in this case the accumulated penalties have reached only the sum of £17 9s. 6d. In some few instances the proceedings have proved abortive, but these are quite exceptional.

New Aids to Hearing.

AT a recent meeting of the Paris Academy of Medicine M. Hardy showed, for Dr. Mathieu, of Estissac, a number of small instruments intended to collect the sound waves and transmit them to the ears of deaf people through the medium of the teeth and the bones of the cranium. The apparatus consisted of pieces of pasteboard folded in the shape of cigars or flowers, which the deaf person holds between his teeth when being spoken to.

These instruments are only useful in cases of complete deafness, due either to obliteration of the external auditory meatus, or to an affection of the middle ear, with preservation of the sensibility of the auditory nerve.

A precisely similar conclusion with regard to the limits of use of the audiphone, was the result of a discussion on the instrument in the sub-section of Otology at the recent meeting of the British Medical Association at Cambridge.

The British Soldier.

OUR contemporary, the *United Service Gazette* lately commented on the evils of the system now in force of training an army of boy soldiers, and remarked that in a mere money sense the loss to the country caused by desertion and enlisting weakly lads is enormous. It is true, perhaps, that just at present an improvement has taken place in the physique of the recruits; but so long as the conditions of service remain what they are we do not expect any such improvement to be more than very temporary indeed. We are somewhat anxious to learn what has been the actual state as regards military efficiency of the young soldiers now in Afghanistan. There is, however, no proper means of making a trustworthy comparison on this point, for the simple reason that there are no *old* soldiers to compare them with; but on all previous occasions—more especially throughout the campaign of the Mutiny—it was proved that whereas old soldiers of fourteen and even seventeen years' continuous service in the plains were able day after day to execute long marches, often meeting and beating the rebels on the way, or at the end of the march, the *young* lads, then newly out from England, unable to undergo such exertions, and to withstand such fatigues, had to *be carried*, thus, instead of adding to the effective *force*, becoming so many incumbrances.

The Health-Rate of Dublin.

THE mortality for the week ending Saturday, August 21st, in twenty large English towns, including London (in which the rate was 21·3) was equal to an average annual death-rate of 24·3 per 1,000 persons living; in Glasgow the rate was 19·5; and in Edinburgh, 17·0.

The average in the sixteen principal town districts of Ireland was 27·9, the respective rates for the several districts being as follow, ranging in order from the lowest to the highest:—Drogheda, 5·2; Lurgan, 6·7; Newry, 12·5; Sligo, 15; Cork, 16·4; Londonderry, 20·2; Galway, 21·1; Limerick, 21·2; Dundalk, 25·6; Belfast, 26.8; Kilkenny, 27·0; Wexford, 27·5; Waterford, 30·6; Queenstown, 36·1; Dublin, 37·3; and Clonmel, 40·6.

In the Dublin district the deaths represent an annual rate of mortality of 37·7. Fifty-one per cent. of the deaths were of children under five years of age, 72 being of infants under one year old. There were 71 deaths from zymotic diseases registered, being 7 more than in the preceding week, and 38 over the average for the 33rd week of the last ten years: they comprise 5 from small-pox, 3 from measles, 15 from scarlatina, 3 from croup, 3 from whooping-cough, 5 from fever (2 typhus and 3 typhoid or enteric fever), 1 from erysipelas, 25 from diarrhœa, 3 from simple cholera, &c. Fifty-four of the 71 deaths in this class occurred amongst children under ten years of age. The registered deaths (5) from small-pox are one over the number for the preceding week, but are less than in any other week since that ending 1st May last. There were only 5 new cases of the disease admitted into the Dublin hospitals during the week; 23 patients were discharged; 3 died; and 48 remained under treatment on Saturday last, being 21 under the number in hospital at the close of the previous week. Deaths from diarrhœa, which rose from 9 in the week ending 7th inst. to 23 in the following week, further rose to 25 last week. All of these 25 deaths were amongst children under five years of age.

The Medical Officers' (England) Superannuation Act.

A PARLIAMENTARY return has been issued showing the number of applications made under the Medical Officers' Superannuation Act (England) to boards of guardians for superannuation allowances. From this return it would appear that since the passing of the Act in 1870, out of 649 unions in England and Wales, applications for allowances have been received from medical officers by the guardians of 108 unions. In these unions 122 applications were made, 70 were granted, 50 were refused, and two had not been decided upon at the date of the return. Among the reasons for refusals of applications, we find the following: "the guardians were of opinion that the officer after seventeen years' service, had been sufficiently paid for what work he had done;" in two instances, after forty-one and forty-two years' service respectively, "the officer was comfortably off;" in one instance, after forty-two years' service, the guardians had an "objection to the entire system of superannuation;" in another instance, after twenty-two years' service, because the officer "was not incapacitated by age or infirmity; he left the union for his own advantage." In several instances superannua-

tion allowances were not granted because the guardians held that the officer had sufficient means from other sources, either as private means or as derived from private practice.

Social Condition of Lunatics in Ireland.

Of the 8,490 persons resident in Irish district asylums at the beginning of this year, the probably incurable stood as nearly as possible to the curable as three and a-half to one—a proportion more favourable to recovery than generally obtains; but the subject is involved everywhere in a certain obscurity. The inspectors, however, in their late report say, that it would be quite fallacious to regard the mental contingencies of the insane in respect to their recovery as the grounds on which to establish distinctions in their management or allocation; the most hopeless as to intellectual manifestations, and the most tranquil apparently in conduct for indefinite periods, needing quite as much care and judicious treatment for their own safety and that of others, as the worst or wildest in demeanour.

Investigating the antecedents of the above aggregate, 3,697 belong to the farming and labouring classes—2,594 men, 1,103 women; next in number come domestic servants, no less than 906, of whom the remarkable excess 839, is constituted of females, against 67 males. It is difficult to discover a reason for this disproportion, unless it is to be found in the disappointments, hardships, and isolation of women when removed from their families and friends without protection, and then perhaps having recourse to dissipation.

Seamstresses, too, as a class, would seem to be largely affected by mental diseases, and, relatively speaking, tradesmen working within doors and at sedentary occupations, more than those employed in the open air. Discharged soldiers and policemen number 266, which appears a percentage disproportionate to the respective forces in this country.

Railway Mortality.

From the annual report on the accidents upon the railways of the United Kingdom for the year 1879, recently presented to the Board of Trade, it appears that the total number of persons killed during the past year was 1,032, and the number of injured, 3,513. Of these, 160 persons killed and 1,307 persons injured were passengers. Of the remainder 452 killed and 1,951 injured were servants of the companies or of the contractors; and 420 killed and 255 injured were trespassers and suicides, &c. The proportion of passengers killed and injured from causes beyond their own control, was, in 1879, one in 7,503,000 killed, and one in 934,700 injured; but if the Tay Bridge disaster were excluded from the computation, the proportion killed would only be one in 281,366,500, or less than in any year on record. The report considers the year satisfactory on the whole, but concludes with a hope that the complete adoption of the block and interlocking systems, of continuous foot-boards, with proper platforms, and especially of improved brake-power, will no longer be delayed.

Observation Wards in General Hospitals.

At an adjourned meeting of the Corporation of Dublin, held on August 23, the Town Clerk read a letter from the Public Health Committee, representing that the Council would, in pursuance of a recommendation contained in the report of the Royal Commissioners on the sewerage and drainage of the city, invite the several hospitals of the city to establish "observation" wards, and to inform the Council of their intentions in the matter before the next grants to the hospitals were considered. The intention is that means should be provided by which a patient suspected of infectious disease might remain under surveillance until all doubt respecting the nature of the disease was set at rest.

Psychologists Beware!

The *Union Medicale* reports that Dr. Legrand du Saull, one of the celebrated alienist physicians of Paris, was recently prosecuted for defamation, he having related, at a meeting of the Société Médico-Psychologique, the case of a person who, according to his view, was insane—his account of the case appearing in the journal of the Society. When this person was liberated from the asylum in which he had been detained, he immediately brought an action against the narrator of his case. Dr. Legrand made no reply to this strange accusation, but the tribunal in its judgment, exonerated him from all penalty, inasmuch as the report of a learned society—published without any intention to do harm, and purely with a scientific object—does not fall within the application of the law.

The Social Science Association.

Arrangements are in progress for holding the approaching congress of this association in Edinburgh. As has already been announced, Lord Reay, D.C.L., is to be the president. The names of the presidents of the departments of Jurisprudence and Art have not yet been intimated. The Right Hon. Sir Walter Crofton, C.B., is to be the chairman of the "Repression of Crime" section; while the "Education" department is to be presided over by Lord Balfour of Burleigh; the "Health" department by John Beddoe, M.D., F.R.S.; and the "Economy and Trade" department by Sir U Kay-Shuttleworth.

Treatment of Diphtheria.

M. Crequy (*La France Médicale*) commences his treatment of diphtheria by removing the false membrane with a forceps; he endeavours by a twisting motion to remove the membrane, without breaking it, in as large a piece as possible; he then with a sponge dabs the denuded mucous surface with a solution of tannin. He never hesitates to adopt this method in all cases.

The "Prelim" at the London College of Surgeons.

Upwards of 500 candidates have entered their names for the forthcoming preliminary examination in arts, &c., for the diploma of Member or Fellow of the Royal College of Surgeons of England, being the largest number on record.

The Dangers of Chloroform.

Two deaths following the administration of chloroform for medical purposes have recently occurred; one, that of a lady at Liverpool, took place in the surgery of a dentist, the deceased being described by her regular medical attendant as of "sound constitution." No blame can possibly be attached to anyone, but the accident serves to point to the necessity for abandoning chloroform in favour of some anæsthetic not so often attended with fatalities. Especially is this the case since the lay papers seem to take fright at the very name, chloroform, and spread the terror of it among the public. Only this can explain the nonsensical statements made in connection with an event like that under notice. One paper, a very respectable one, prints that "the inference was that the influence of the drug had stopped the heart!" In the second case a patient died in the London Hospital, but details are at present withheld from the press for some reasons not yet apparent.

Scavenging in Dublin.

The Dublin Corporation had last week under consideration a Report of the Committee appointed in February last to deal with the question of public and domestic scavenging. The Committee have recommended that the Corporation should take entire charge of the scavenging, and have the same carried out by their own staff under a competent manager. The expense of the department is estimated at £28,700 per annum, or a trifle over one shilling in the pound on the city rates. The report has been adjourned for a future meeting of the Council.

Ether Hypodermically in Sciatica.

Dr. Comegys recommends, in the *Union Médicale*, the hypodermic injection of sulphuric ether for the treatment of sciatica. He cites two cases, one in detail, which he cured by this plan. Three drops of ether are injected, at intervals of twelve hours. The injection need not be a deep one, and it does not bring on any consecutive unpleasant effects. Dr. Comegys is inclined to think that the same injection might be successful in the case of tic douloureux, for which Dr. Marino recommends hypodermic injection of ergotine.

A Nurse Charged with Assault.

A nurse named Winter has been charged before the Margate magistrates with ill-treating a lady under her care, the patient being of unsound mind. The details of the case are scarcely calculated for reporting, their interest centreing in the fact that the invalid is related to a member of the judicial bench. The matter ended in a discharge by the magistrates, but will form subject of inquiry to the lunacy commissioners.

The end of "Dr." Buchanan.

At Philadelphia the grand jury last week indicted Dr. Buchanan for selling bogus diplomas. The doctor, who was out on bail, would have been arraigned for trial on the 17th, but the previous night he jumped from the ferry-boat on the Delaware river, and was supposed to have committed suicide; but as the body has not been found the police think he may have escaped.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 21, Bombay 27, Madras 28; Paris 26; Geneva 13; Amsterdam 22, Rotterdam 24, The Hague 23; Copenhagen 26; Stockholm 26; St. Petersburgh 41; Berlin 38, Hamburg 28, Dresden 30, Breslau 38, Munich 31; Vienna 22, Buda-Pesth 42; Rome 32, Turin 32; Alexandria 44; New York 30, Brooklyn 23, Philadelphia 22, and Baltimore 20 per 1,000 of the population.

We observe with satisfaction that Mr. Joshua Jacob, a Limerick quaker shopkeeper, who has been for the last year or two trying to achieve martyrdom by refusing to have his children vaccinated, has betaken himself, his ignorant prejudices, and his bad example, out of the country, *oh si sic omnes!* If he would only establish an anti-vaccine new Jerusalem, where he is gone to, and take into his community the mischievous and illiterate fanatics, whe are disturbing the peace of our country by their resistance to vaccination, what a benefactor to his species, at home, the poor silly man would be.

The following are the questions proposed for the Boylston Prize Essay for 1881: 1. The Effects of Drugs, during Lactation, on either Nurse or Nurseling; 2. Injuries to the Back, without apparent mechanical lesion, in their surgical and medico-legal aspects. The author of a dissertation considered worthy of a prize on either of the subjects proposed for 1881 will be entitled to a premium of three hundred dollars. The questions proposed for 1882 are: 1. Sewer-Gas (the gas found in sewers); What are its Physiological Effects on Animals and Plants? an Experimental Inquiry. The author of a dissertation on the above subject considered worthy of a prize will be entitled to a premium of three hundred dollars. 2. The Therapeutic Value of Food administered against or beyond the Patient's Appetite and Inclination. The author of a dissertation on the above subject considered worthy of a prize will be entitled to a premium of two hundred dollars.

Literature.

RECENT WORKS ON MINOR SURGERY. (a)

It is difficult to understand how the medical student of two or three generations back managed to acquaint himself with the details so admirably furnished now-a-days in the numerous little handbooks on minor surgery. It is true that many, nay, the majority of those who acquired their knowledge thirty or forty years ago, may have failed to do more than grasp the merest outlines of their duties during their student career; it must have been so; but this, as being sheer practical experience, served them as an admirable basis for future work in the same direction, so that it

(a) 1. "Practical Surgery." By J. Ewing Mears, M.D. Philadelphia: Lindsay & Blakiston. 1878.
2. "Manual of Surgical Operation." By Joseph Bell, F.R.C.S. Edin. Fourth Edition: Edinburgh: Machlachlan & Stewart. London: Simpkin & Co. 1879.
3. "Minor Surgery and Bandaging." By Christopher Heath, F.R.C.S. Sixth Edition. London: J. & A. Churchill. 1880.
4. "The Essentials of Bandaging." By Berkeley Hill, M.B. Lond., F.R.C.S. London: Smith, Elder, & Co. 1880.
5. "Surgical Emergencies." By William Paul Swain, F.R.C.S. Third Edition. London: J. & A. Churchill. 1880.

might almost be doubted whether the student of this age is actually in a better position to learn because of the many aids ready to his hand. Be this as it may, however, it is difficult to say anything, except in the way of praise, of the five little manuals we have under review.

Dr. Mears' work on "Practical Surgery" can hardly be deemed a hand-book on "minor" surgery, seeing that he gives directions for amputations at the joints, the thigh, and arm. The directions, however, are clear and terse; the chapter on "bandaging" is excellently written, and illustrated in a way to be serviceable as a guide in performing the various operations described. The figures throughout are well executed, and the work, taken altogether, is a judiciously-prepared, neatly-presented manual.

Mr. Joseph Bell's "Manual of Surgical Operations" has obtained a hold on the affections of students but little inferior to that possessed by Mr. Heath's Guide. The four figures showing the position of the incisions made in various ligatures and amputations, have done much to assist vast numbers of students in remembering the somewhat confusing list of operations of this kind. Like all the figures in the work, they are boldly and clearly drawn, and nothing more is introduced than is absolutely necessary to an accurate comprehension of the text. The work is so well and favourably known that it is not requisite to say anything, except that this edition maintains the excellence of previous ones, the author having made a rigid supervision in order to keep it abreast of modern progress in surgery.

Mr. Heath's "Minor Surgery and Bandaging" almost deserves the title of the house-surgeon's bible, so inseparable a companion is it with him. This sixth edition of the work is essentially a reprint of the fifth, the only alterations made being such as were rendered necessary by recent advances. A few new wood-cuts have been added to render the text more easily understood in certain places, but the style and character of the work remain unchanged.

"The Essentials of Bandaging" is likewise a very favourite book with students, and deservedly so. As a guide to the duties that come within the sphere of the house-surgeon and dresser it is most valuable; and in its directions for performing a number of small, but delicate operations, such as douching, syringing, dressing, plugging the nares, extraction of teeth, &c., &c., it affords information in a way that never fails to interest the reader and give him an accurate knowledge of the details to be observed.

By-the-way, Mr. Hill says (page 207), "the pulse gives the earliest indication of syncope." This may well be doubted, and more implicit reliance placed on the evidence afforded by the respiration. The physiological effects of chloroform inhalation pursue a definite sequence, and the last of these is that with which the heart is concerned. Prior to its inhibition, respiration is seriously interfered with, and this, we take it, should be the point the chloroformist should direct his attention to. The pulse is almost useless as a guide to approaching syncope. It can only indicate existing collapse. As a manual of minor surgery Mr. Hill's "Essentials" ranks with the best works on the subject.

The "Surgical Emergencies" by Mr. Swain is exactly what its title expresses. It is the most valuable companion the general practitioner can possess to guide him in those sudden cases when he is at a moment called on to exert himself to save life or limb. Mr. Swain has made the wisest possible selection of instances; and in particular are the chapters on emergencies connected with parturition and poisoning, likely to serve the student in good stead. The final chapter on apparatus and dressings might, perhaps, more fully describe the extemporary arrangements that can be made with the aid of the commonest materials, and a little ingenuity. It is not well to trust too implicitly to common sense in these matters. As a plain and reliable guide to action in cases of emergency, however, this little book cannot be too highly esteemed.

PRACTICAL HINTS ON THE PRESERVATION OF THE TEETH. (a)

This is a pamphlet of a well-known type, consisting of eight or ten meagre pages of information of more than doubtful value, far from clearly expressed, and having the author's name and address appended. We notice it merely to remark that we imagined such publications were out of fashion with qualified dentists, and especially with members of the Association of Surgeons practising Dentistry—a society which was founded with the loudly-proclaimed purpose of promoting a rule of professional conduct superior to that acted upon by dentists of an inferior grade.

(a) "Practical Hints on the Preservation of the Teeth." By J. Stevenson, M.R.C.S., L.D.S. London: J. & A. Churchill.

THE ELEMENTS OF INDIAN HYGIENE. (a)

This little book, true to its title, contains such elements as may be useful to the young student of Indian hygiene. But why does its author conceal his *rank* in the service to which he belongs? Is it not the case that medical officers are said to be very touchy on the subject of rank? and yet on the title page of the work before this "guinea's stamp" is ignored altogether. The usual subjects of books on Hygiene are here shortly touched upon, more especially in their relation to the civil population. With regard to the sanitary conditions of towns and villages, the difficulty of effecting improvements in them is noticed, and various rules laid down with this object in view; unfortunately, however, as with ourselves in England, so in India, towns and villages grow up, and are growing up, in positions having regard more to trade, commerce, or other material advantages than to considerations of a purely hygienic nature; the ways of the natives of India also are not our ways, nor their sanitary standard our sanitary standard. But it is well to know that the subject of village sanitation has attracted the serious attention of the Government of India, and that officials are now engaged in establishing, as far as that is possible, a working system regarding it. At page 75, a very sad account is given of the condition in which the hill sanatorium, Wellington is said to be—an account, surely, taken from reports of old date—for as we write, that for 1878, by the Sanitary Commissioner of Madras, is before us. According to the account given at page 131 of the latter document, the drainage, water supply, and conservancy at the station named were all *good*.

ROCKY MOUNTAIN HEALTH RESORTS. (b)

Not long ago we heard much of inflammation as being the destructive agent in cases of pulmonary phthisis, and much stress was accordingly laid on rest and apyretic remedies as most important curative agents. That inflammation has some part in hastening on destruction of lung substance and in preventing the repair of tissue already diseased must be admitted, and the fact will serve to explain the very beneficial action exercised over cases of advanced phthisis, with congestion of lung around a cavity by very small doses of tartarated antimony.

To regard all cases of progressive phthisis as inflammatory in their nature is a retrogression and brings one to think of the old-fashioned treatment of the disease by the warm air of a cow-house and all manner of expectorant remedies. In contrast to these ideas the views and practice of Dr. Denison stand in bold and conspicuous contrast, and we would commend to the attention of a consumptive, who has had enough of rest and digitalis and quinine pills, chapter xvii., on Camping out at Colorado. Let the consumptive invalid "on his arrival at Colorado remain ten or fourteen days in one of the lower towns, Boulder, Denver, Pueblo, or Canon City, as the case may be, and from thence advance gradually by rail, horseback, or wagon, to higher levels, as the enfeebled lungs accustom themselves to the rarefied air." It seems that in the pre-railroad days, when all who crossed the plains were compelled to do so in a wagon, the degree of improvement was greater among the consumptive invalids than it is at present, because then they were obliged, even if they left home on a mattress, to live wholly in the open air, sleep under the stars, and often do their own cooking.

In this chapter on "Camping Out" are many very useful

(a) "The Elements of Indian Hygiene." By John Lucas, F.R.C.S, &c., Her Majesty's Indian Medical Service.

(b) "Rocky Mountain Health Resorts." An Analytical Study of High Altitudes in relation to the Arrest of Chronic Pulmonary Diseases. By Charles Denison, A.M., M.D., Reporter to the International Medical Congress, Philadelphia, 1876. Boston: Haughton, Osgood & Co. London: Trübner & Co. Pp. 192.

hints as to the routes and plan of provisioning, with its cost, that, for the invalid who goes to Colorado with *the determination to get well*, are of great practical utility. Colorado College stands, we may here remark, at an altitude of 6,000 feet.

The general effect of the respiration of air at various degrees of elevation has been duly considered by Dr. Denison.

We will refer first to a case of chronic bronchitis, which, when persistent, so often leads to actual lung disease. In 1876 a clergyman from Brooklyn came to Colorado with obstinate bronchitis and some blocking-up of the upper third of the right lung, commencing fibroid phthisis probably. He for a time found the high elevation try his breath severely, but after seven months of horse-back exercise over the mountains the rattling noises in his chest had disappeared, and the imperfectly used upper part of the right lung was rapidly being opened to complete and healthful respiration.

Space does not permit us to refer at any length to the analysis of the tables of cases of hæmorrhagic phthisis. The conclusion come to as the result of the examination of the statistics is thus given by the author: "Therefore *hæmorrhagic cases are to be preferred for the high altitude treatment next to the inflammatory group.*" P. 136.

Hæmorrhages from the lungs without cavity are rare in the high altitudes, but where there are cavities and also a liability to hæmorrhage, we gather that Denison considers he has a class of case which, according to table xiii, do not do well at a high elevation.

Throughout the whole volume abundant evidence comes forward of the immunity of inhabitants of elevated regions from pulmonary phthisis, and of the remarkably curative action of a dry rarefied air in promoting the cure of the disease. These therapeutic views adapt themselves reasonably to the more modern notions of phthisis being a disease of germinate and infective origin, and give an insight into the reason why medical treatment has as yet been so very unsuccessful. Dr. Denison's book is full of facts and observations, deals very little in theories, and is quite the work to be read by one practically concerned in the treatment of pulmonary consumption.

A HANDBOOK OF PHYSICAL DIAGNOSIS, COMPRISING THE THROAT, THORAX, AND ABDOMEN. (*a*)

ANY work which puts before us a more or less complete account of the signs upon which we rely for the diagnosis of disease is entitled to a high meed of praise. With the constant tendency which exists to indulge in quackery, cloaked as it is in most cases by a display of *quasi* scientific phraseology, great importance should be attached to an accurate analysis of the signs upon which the diagnosis of morbid states is based to enable us to obtain the key to a rational system of therapeutics. No doubt it saves a world of trouble to treat symptoms as they separately arise, and as each disappears in the natural evolution of diseased processes we can complacently take to ourselves the credit of effecting what was beyond our control, or flippantly talk of "curing" that which terminated in spite of our interference. It is, unfortunately, true that in many instances the nature of a case may be so obscure as to afford scarcely any grounds for positive diagnosis; still, if medicine is to be regarded as at all progressive, the number of such cases must steadily diminish, and it is to the investigator of the physical signs of disease, with the aid of the pathologist and morbid histologist, that we must look for this salutary advancement.

Dr. Guttman's work consists of five sections. The first deals with the general examination of the patient; the second with the organs of respiration; the third with the organs of circulation; the fourth with the examination of the abdominal organs, and the last with the examination of the larynx. It will be noticed that no reference is made to the nervous system, nor to the examination of the diseased conditions by means of the ophthalmoscope. In this respect the work is incomplete as a handbook of physical diagnosis, though as a concise epitome of the methods pursued in the clinical examination of the thoracic and abdominal organs in health and disease it is an accurate and valuable addition to the literature of medicine.

Throughout the work, however, in the different sections some errors of omission exist which one would not expect from so careful an author as Dr. Guttman. Thus in the description of the changes in the colour of the skin under different diseased conditions, no allusion is made to melanæmia, or to the "gipsy-colour" (Vagantenfärbung) which we have seen so often lead to a mistaken diagnosis of Addison's disease. In dealing with the signs of cardiac diseases the existence of double apex impulse in extreme eccentric hypertrophy of the left ventricle is a point which would seem to be worthy of notice, whilst such a full and succinct account is given of the circumstance under which the heart's impulse is absent.

Again, in the chapter on palpation in diseases of the peritoneum, no mention is made of the direct sense of fluctuation, an important evidence of the existence of fluid where the peripheric method is not practicable, as in case of great œdema of the abdominal wall. In cases, moreover, where the amount of fluid in the peritoneum is very small, peripheral fluctuation may be detected by getting the patient to rest upon his knees and elbows in bed, the fluid gravitates towards the region of the umbilicus, and its presence there can be determined. In referring to the existence of friction phenomena in the peritoneum reference might have been made to that granular condition of the omentum which under certain circumstances gives rise to a sense of friction appreciable to the touch. We had under observation some years ago a case of cancer of the head of the pancreas in which the sense of friction on palpation was so marked as to lead to the diagnosis of localised peritonitis, but the post-mortem examination revealed merely a granular condition of the great omentum, which moved freely over the tumour, and was entirely free from any traces of inflammation.

But notwithstanding these and a few other minor omissions we must give the author credit for producing a work which represents the progress of medicine, as far as it goes, up to the most recent date. The description of the methods available for the examination of morbid states of the lungs is full, concise, and accurate. The reader will be specially interested in the views put forward as to the causes of amphoric resonance and tympanicity. The quality of percussion notes as to pitch is referred to at considerable length, and probably it will have the effect of rendering the use of the somewhat obscure terms, dulness and resonance, less frequent than heretofore. In the section upon the examination of the organs of circulation, we would direct particular attention to the account given of venous and arterial pulses, and the cases of reduplication of the sounds of the heart. We quite concur in the view that in the great majority of cases, double first, or second sound, depends not on a synchronism in the systole of the two ventricles, or on the closure of the two sets of semi-lunar valves, but upon a non-synchronous tension of the individual segments of the valves. It is to be regretted that in dealing with the signs of mitral stenosis the author should retain the use of diastolic murmur, which though not incorrect, is not as distinctive as the term presystolic murmur introduced by Fauvel.

In conclusion, we may, without hesitation, commend Dr. Guttmann's handbook as a scientific exponent of the most recent views on physical diagnosis, and we can congratulate the Council of the New Sydenham Society for having translated a work which is highly creditable to the German School of Medicine.

(*a*) "A Handbook of Physical Diagnosis: Comprising the Throat, Thorax, and Abdomen." By Dr. Paul Guttman. Translated from the Third German Edition by Alex. Napier, M.D. London: The New Sydenham Society.

PHARMACOLOGY AND THERAPEUTICS. (*a*)

THERE is always something fascinating and suggestive about Dr. Lauder Brunton's writings. A master of the methods and aims of physiological investigation, he is peculiarly happy in the manner in which he brings his results before us, and leads us to look forward to what has to be done in the future. In the work before us, which consists of the Gulstonian Lectures for 1877, Dr. Brunton has endeavoured to show how the progress of therapeutics, in other words, the beneficial *practice* of medicine, is aided by an exact knowledge of the action of drugs, such knowledge being gained by experiment on animals and otherwise.

(*a*) "Pharmacology and Therapeutics; or, Medicine Past and Present." By T. Lauder Brunton, M.D., F.R.C.P., F.R.S., &c., &c. London: Macmillan and Co. 1880.

Commencing with an interesting sketch of the history of medicine in the past, and of the methods by which its study has been pursued, the author goes on to show how the results of experiments on the physiological action of drugs are brought to bear upon therapeutics. This is done by tracing the history and methods of pharmacology, that is, the study of the physiological action of drugs, and its application to clinical medicine through pathology. Had we space we should like to have referred at length to many points of great interest in this book, the perusal of which has afforded us great pleasure, and given us much food for thought. As it is, however, we can only recommend it to our readers. It shows us the great strides which medicine is making now that, as Dr. Brunton says, "the path she follows is the right one." There can be little doubt that it is by a proper application of our knowledge of the physiological action of drugs, that their true therapeutical value will be arrived at, and it is by the combined labours of such men as the author of this book that the practice of medicine will, in time, become an art of scientific certainty instead of a system of haphazard empiricism.

Correspondence.

ILKLEY WELLS AS A HEALTH RESORT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a holiday tour round Yorkshire I found myself last week in the neighbourhood of Ilkley Wells and Ben Rhydding, and as little seems to be known of these parts by the profession generally, my experience of a few days spent there may not prove uninteresting. Protests have been made from time to time that physicians are too much in the habit of sending patients abroad, regardless of the claims of our health resorts at home, and not infrequently forgetful of the trials and troubles to which invalids are subject before reaching the fashionable spots on the Continent. But then *it is fashionable*, and physicians are unfortunately not beyond the pale of its influence, arguing on the score of the patent medicine-vendor, that "it does not do to let people know too much." Few have the courage of Dr. Kent Spender, of Bath, to go and test these cure-all places in their own person, to write publicly the results of practical experience—*vide* his opinions of the Engadine—and advise patients to patronise the healthier resorts of the United Kingdom, rather than the depressing mist-producing valleys of Switzerland. But to my subject: Among the many noted "dales" of Yorkshire, the valley of the Wharfe stands pre-eminent for the beauty of its scenery, both in the wild grandeur of its upper course, and the extended and fertile vale into which it gradually expands. After passing under the lofty crags of Kilnsey, forcing its impetuous way through the rude and massive rocks which form the ineffectual barrier of Bolton Strid, and winding amidst the luxuriant woods and hills, where stand the ruins of the celebrated Bolton Abbey, the Wharfe at length reaches the picturesque village of Ilkley, the Olicana of the Romans. The southern side of the valley is here bounded by the lofty range of rocky hills called Rombalds, or Rumbles Moor, from which gushes in never failing force the spring of pure cold water for which Ilkley is famed. The valley of the Wharfe, now called Wharfedale, has been truly described as the most beautiful and healthy valley in England, overlooking which, 500 feet above the level of the sea, stand the two magnificent Hydropathic establishments of Ilkley Wells and Ben Rhydding. As, however, I cannot speak from personal experience of the latter establishment, having stayed at the former during my unofficial visit, I must confine my remarks to Ilkley Wells Sanatorium and its surroundings.

This Mansion, at present occupied by Dr. Joseph F. Leeson, is a large and most beautiful structure, in the Italian Palazzo style, replete with every convenience, and contains magnificent dining, drawing, recreation, billiard, and news-rooms, thirteen private sitting-rooms, with all the bed-rooms and offices requisite for such an establishment. The atmosphere during the few days of almost uninterrupted warm weather of my visit was dry and exhilirating, and the breeze which swept over the adjacent moorland sharpened the appetite amazingly. In the winter season the house, with its spacious corridors for promenade, is warmed throughout by means of Sylvester's Patent Warm-Air Apparatus, and as the soil is gravelly, and the air generally free of mists, winter residence here would be clearly indicated in many cases hitherto sent abroad.

During my visit, about one hundred persons sat at the public dinner table daily; the food was bountiful, of excellent quality, and the *cusine* all that could be desired. It is not strictly a hydropathic establishment, as Dr. Leeson is not the class of man to stick at a hard and fast line of treatment. There are others beside patients, who, like myself, take up a temporary residence, and are not under medical care. Liquids stronger than water may be indulged in moderately; the quietly disposed can obtain quietude, and those in search of recreation and amusement will find both in this expansive and well-ordered home. Dr. Leeson is courteous, appears to have the confidence of his patients, is ever on the alert in search of pleasant drives by day, and amusements at night for them, and possesses those essential characteristics for the head of a huge establishment of this kind, the *suaviter in modo* with the *fortiter in re*. It therefore gives me much pleasure to point out in the pages of this journal another health resort at home, whose claims on the profession will be firmly substantiated by a personal visit when in search of health, as was done by, Sir,

YOUR PERIPATETIC CORRESPONDENT.

BAILLIERE *v.* BEANEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—With reference to a letter which has recently appeared in the *Medical Times and Gazette*, we wish it to be understood by the profession that none of the family of the late Mr. Baillière, of Regent Street, have had any interest in this business since we purchased it ten years since of the widow.

We are still the agents and correspondents of those high-class houses of Paris and Madrid bearing that name, but have no connection, business or otherwise, with Mr. F. Baillière, of Melbourne, plaintiff in the action of "Baillière *v.* Beaney."

We are, &c.,

ALBERT ALFRED TINDALL.
GEORGE COX.
(Baillière, Tindall, and Cox.)

20 King William Street, Strand, London.

LUNACY CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am a workhouse medical officer, and as such I had frequently signed the certificates of lunacy for cases of that disease arising among inmates previous to the Dangerous Lunatic's Amendment Act. Since then the magistrates say my certificate is not valid, and after I have gone to the trouble of obtaining and filling up the necessary forms, and a promise of admission for my patient to the lunatic asylum, I must hand him over to the dispensary doctor whom the magistrates call in to know if the patient is a dangerous lunatic. Of course the dispensary doctor gets his fee and the *éclat* which naturally attaches to his implied legal superiority. I am a member of the Irish Medical Association; I believe my present unenviable position is, in a great measure, the result of the neglect of that body. Perhaps you could answer these questions:—

1. Is my certificate of lunacy in the case of a pauper inmate valid, and should the magistrates act on it!

2. Is my certificate of lunacy in the case of a private patient of small means whom his friends want to get admitted as a non-paying patient to the district asylum, valid?

Until the passing of the late Act I had no doubt on these heads, but since then I, in common with other non-dispensary doctors, have been placed in a curious position.

Yours, &c.,

M.D.

[By the 10th section of the Dangerous Lunatics Act (30 & 31 Vic., cap. 118, "Irish Medical Directory," page 497) it is declared that the magistrate before whom the lunatic is brought shall call to his assistance the dispensary medical officer, and upon his certificate alone can the said lunatic be committed. This law applies only to the case of *dangerous* lunatics. Any medical practitioner may examine and certify a harmless lunatic, but if he expects to be paid he must make his bargain with the lunatic's friends, for there is in Ireland no law either to oblige a Poor-law medical officer to certify or to secure pay-

ment of a fee for doing so. We are not sure that the L. G. B. auditor could sanction such a fee paid to a workhouse medical officer for certifying a workhouse patient. Our correspondent's certificate is perfectly valid in every case, save that of a lunatic apprehended by the police "under circumstances denoting a derangement of mind and a purpose of committing some crime for which such person would be liable to be indicted." Probably our correspondent would have refrained from his unworthy and unjust shot at the Irish Medical Association, if he had known that in the original Act the duty of certifying a dangerous lunatic was imposed on the dispensary doctor "without fee or reward," and that it was solely by the influence of the Association that the 14th clause of the Amendment Act was inserted which gives a fee for such work.—Ed. M. P. & C.]

HYPODERMIC INJECTION OF PILOCARPINE FOR ASTHMA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having seen in the *British Medical Journal* of the 7th August a communication from one of its correspondents in which the hypodermic injection of pilocarpine in asthma is favourably spoken of, and, unfortunately, being for many years a sufferer from that distressing affection, I was induced to give the drug a trial; accordingly having procured a supply, and injected ¼ grain of it at bed-time, I awaited the result in *breathless* anxiety. It soon followed, but not indeed in the manner expected or wished for, the effect on the dyspnœa being simply *nil*, but as if to compensate for its inertness in relieving the pulmonary difficulty, the medicine developed its physiological action in a most unexpected and disagreeable way on the genitals, causing violent priapism, attended with an urgent desire and (owing to the extreme rigidity of the penis) total inability to micturate. This unpleasant state of things continued for several hours, and only yielded at length to repeated doses (3 gs.) of bromide of potassium with four drops of tinct. of aconite (B.P.) in each. As my professional brethren may not be aware of this effect of the pylocarpine on the system, I think it only right (with your kind permission) to direct their attention to it through the columns of the *Medical Press and Circular*.

I am, dear, Sir,

Your obebient servant,

Thos. Carey, M.R.C.S.E.,
Late Resident Medical Officer, Barrington's Hospital, Limerick.

Prize Essay on the Laws of Hygiene.—The British soldier in India is to be instructed in the laws of hygiene, to which end the Government has offered a prize of £100 for the best manual on the subject. The adjudication will be made after March 1 next year, before which date competitors are requested to send in their primers to the Government of India, Military Department. The prize will be adjudicated by a committee consisting of the Surgeon-General, Her Majesty's Forces in Bengal, and Principal Medical Officer, Her Majesty's British Forces in India, the Sanitary Commissioner with the Government of India, and an officer of the Quartermaster-General's Department, to be appointed by His Excellency the Commander-in-Chief. Government will not award the prize unless a manual is produced in all respects suitable for the purposes for which it is required.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," 'Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. C. E.—The analyses are, every one, thoroughly reliable, and have been made by gentlemen whose experience in this particular work is the most extensive possible. Your doubts are not unnatural, but you may place implicit trust in the information given to our readers. To the other question, No. A coroner should only express himself adversely to a practitioner when there is ample justification for an unusual proceeding. We remember the instance, and have noted it for future comment.

Dr. Thompson.—The Royal College of Physicians. The zealous guardianship of professional prestige is a first duty with a body which is constituted the highest court of appeal.

Sanitas should consult an elementary treatis on chemistry. We do not write for first year students as a rule, but we appreciate, nevertheless, the artless trustfulness of a correspondent who decides to repose confidence in our opinion whether oxygen should be termed a gas. We *think* so. Yes, we have seen sulphur burned in oxygen, and must respectfully decline "an easy *gradus chemicus, or outlines of physical phenomena.*" Our office abounds in phenomena just now; we can easily dispense with a few.

Exmouth.—Not if there is a demurrer raised to the action of the committee. In any case the course should be that you suggest.

VACANCIES.

Boyle Union, Keadue Dispensary.—Medical Officer. Salary, £120, with fees, and £10 as Medical Officer of Health. Election, Sept. 6.

Flintshire Dispensary.—House Surgeon. Salary, £100. Candidates must be conversant with the Welsh language. Applications to the Hon. Sec. on or before Sept. 7.

New Ross Union, Fethard Dispensary.—Medical Officer. Salary, £100, with fees. Election, Sept. 7.

Newry Union, Mountmorris Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election, Sept. 6.

Wimborne and Cranborne Union Rural Sanitary Authority.—Medical Officer of Health. Applications (stating salary required) to the Clerk not later than Sept. 17.

APPOINTMENTS.

Annington, B., M.D., M.R.C.S.E., has been re-appointed Medical Officer of Health for the Borough of Cambridge.

Barnes, H., M.D., Consulting Physician to the Cumberland and Westmoreland Convalescent Institution at Silloth.

Ewart, W., M.B., M.R.C.P.L., Pathologist and Curator of the Museum of the Hospital for Consumption and Diseases of the Chest, Brompton.

Logan, F. T. B., M.R.C.S.E., Medical Officer for the First (A) District and the Small-pox Hospital of the Bedminster Union.

Masson, W. H., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for Districts Nos. 1 and 2 and the Workhouse of the Daventry Union.

Meller, C. M., M.D., M.R.C.S.E., L.S.A., Medical Officer to the Carisbrooke District of the Isle of Wight Union.

Milne, T., M.A., M.D., Medical Officer of Health for the Borough of Accrington.

Mills, S., B.A., L.R.C.P.Edin., Medical Officer to the Donaghmore Dispensary, Newry Union.

Orpen, C. H., M.R.C.S.E., L.S.A., Medical Officer to the Workhouse of the Bedminster Union.

Palmer, B. A., M.D., Medical Officer to the Crossmaglen Dispensary, Castleblaney Union.

Pritchard, J. E., B.A., M.B., M.R.C.S.E., L.S.A., Resident Medical Officer to the Swansea Hospital.

Roxburgh, R., M.B., Honorary Consulting Physician to the West of England Sanatorium.

Stonham, Mr. C., Obstetric Assistant to University College Hospital.

Births.

Juler.—Aug. 22, at Wimpole street, Cavendish square, the wife of Henry Juler, F.R.C.S.E., of a son.

Kevin.—Aug. 22, at 144 Donegall Pass, Belfast, the wife of Charles Kevin, M.D., of a son.

O'Carroll.—July 31, at Beguia, St. Vincent, West Indies, the wife of Dr. M. O'Carroll, Medical Officer, Police Magistrate, and Coroner of the Grenadines, of a son.

O'Donovan.—Aug. 21, at Mount Haigh, Kingstown, the wife of Jeremiah O'Donovan, L.R.C.S.Ed., of a son.

Smith.—Aug. 22, at Carlton House, Pembridge Villas, Bayswater, the wife of E. Stanley Smith, M.R.C.S.E., of a son.

Wallace.—Aug. 22, at 243 Hackney road, E., the wife of Frederick Wallace, L.R.C.P.L., of a son.

Marriages.

Lapper—FitzGerald.—Aug. 24, at Rathfarnham, co. Dublin, Edwin Lapper, L.K.Q.C.P.I., 5 Highfield Terrace, Rathgar, to Caroline, youngest daughter of the late James FitzGerald, Solicitor, of this city.

Deaths.

Brims.—Aug. 13, at Pitlochry, N.B., Elizabeth, relict of the late James Brims, M.D., of Mount Villa, Burnley, aged 48.

Burges.—July 23, at Meerut, India, killed by a fall from his horse, William Armstrong Burges, M.D., A.M.D., Surgeon in charge of R.A., second and much-beloved son of Francis Carleton Burges, M.D., Fethard, co. Tipperary.

Heywood.—Aug. 18, at Fendleton, H. J. Heywood, M.R.C.S.E., aged 45.

Knowles.—At Newmarket road, Cambridge, E. Knowles, M.R.C.S.E.

Theed.—Aug. 20, at The Vicarage, Lower Halstow, Kent, the residence of his brother, Frederick Theed, F.R.C.S., formerly of Rhyl, aged 66.

Whitmore.—Aug. 25, at Castle Hill, Ealing, John Whitmore, M.D., Medical Officer of Health for Marylebone, aged 69.

AN ANALYSIS OF FIVE HUNDRED CASES OF PERFORATION OF THE MEMBRANA TYMPANI. (a)

By GEORGE P. FIELD,

Aural Surgeon to St. Mary's Hospital.

(*Continued from page* 170.)

Dropping certain fluids into the ear may make a hole in the drum head. I have had two from pouring in turpentine. One in a gentleman who in the night poured it in by mistake; and another case at the hospital in which the mother put it into her child's ear. I said to her, "What did you do it for?" She replied, "You see, sir, the child was in such agony, that I thought it required a strong remedy, and turpentine was the only thing I could lay my hand on."

One case from pouring urine into the ear. One case occurred from violent syringing, that of a lady who had consulted a doctor for deafness. She said he immediately produced an immense syringe, and, I am sorry to say, as is not uncommon, without attempting to look at the ear, began to pump away until something gave way—the drum-head. This lady at once came up to town and consulted Dr. Bryant, who called me in. When I saw her she was in a critical state with high fever, the whole of the side of the head inflamed, her eyes rolling about, and she was almost mad with the intense pain. As I remarked before, morphia taken internally in these cases is almost useless. She had taken a large quantity of it without getting any relief. I put on eight leeches, and repeated them at intervals five times, and not until she had had forty on did she lose all pain and get out of danger. She made an excellent recovery.

One case from a scald. G. J., a coachbuilder, æt. 18, came to the hospital Jan. 17th, 1880. with a scald in left ear. He stated that he was asleep on the hearthrug, and that his brother, in taking a pot off the fire, let some of the boiling water fall into his ear. In this case, as in the last, the inflammation was very severe; blowing his nose caused great pain, and a whistling sound through the perforation in the drum-head. Leeches were used freely; various weak astringent lotions, such as acetate of lead with opium, were given, and on Feb. 14 the discharge stopped, the perforation shortly afterwards closed, and he regained his hearing. Another case of severe inflammation caused from putting a strong solution of caustic into the ear I had lately. A gentleman living in the country had some ear mischief; what it was I don't know. The doctor, however, gave him a very strong solution of nitrate of silver, and a brush, so "that he might burn it away himself." This he certainly did most effectually, for very little drum-head, or anything else, he left. He came up to town to Dr. Herbert Davies, who sent him on to me, but I have not seen him again.

Traumatic injuries of the drum-head, as a class do well, and these I have found are more likely to close than those produced by disease.

Slit-like openings, caused by a puncture of a sharp foreign body such as a pen-holder, where the sides of the perforation are usually in apposition, are most amenable to treatment. In all cases the sooner the symptoms are attended to, the better. If a discharge is permitted to continue for some time, a round hole is formed from the constent passage of the fluid, and the edges will not so readily unite, as in a recent case of injury where the sides are usually almost in contact. The prognosis depends very much upon the mode of injury, thus falls or violent concussions, such as those produced from a blow on the side of the head or from the explosion of a heavy gun, may not only rupture the membrane, but cause concussion of the labyrinth or permanent injury to the ossicles. In a case sent to me by Mr. Woodman, of Ramsgate, a few months ago, a gentleman ruptured his left drum head from being thrown off a dog-cart. I did not see him until some time after the accident. I found a small perforation, which, instead of closing,

(a) Read before the Harveian Society, May 20th, 1880.

caused a great deal of trouble, giving exit to a small polypoid growth. This was destroyed, but the perforation did not disappear, and he remained deaf. Here there was probably also slight concussion of the labyrinth; the history of the accident made it likely. This was not satisfactory in any way, for he had been for a great many years very deaf in the other ear so that diagnosis by means of the tuning-fork was not quite clear. Of course, if there is simply a rupture of the membrane in one ear and no mischief in the labyrinth, the tuning-fork would be heard better in the injured or deaf ear. In nearly all cases of ear disease, I may remark, this instrument is a valuable help to us in diagnosis.

I will give another obscure case. It is that of a gentleman in the artillery, who came to consult me for extreme deafness, August 25th, 1879. There was no history of deafness in his family. He was totally deaf in the right ear, and could hear the watch only in contact in the left, the membrane of which was perforated. Eighteen years previously he contracted syphilis in India, but had suffered few ill effects from it, and had only been deaf for eighteen months. As he was in the artillery he was, of course, constantly present at heavy gun practice. He had marked disease of both internal ears. The question arose, Was it set up from concussion of the labyrinth from repeated discharge of heavy guns, or was it due to the syphilis? or, in addition, did it arise from sudden shock? as just before the deafness came on he was present when his brother, to whom he was greatly attached, suddenly died under chloroform, an event which at the time caused him the utmost distress and nervous prostration.

Before he came to me, by the advice of Sir William Jenner, he had ungone a long course of mercurial treatment at Aix la Chapelle. If it was not of syphilitic origin the nervous prostration caused by such treatment would increase the disease, therefore Sir William Jenner's opinion was clear. The question arose (1) was it due to syphilis, (2) to the sudden shock, or (3) to gun fire? Deafness from sudden shock caused by distressing news is generally very severe, and comes on in a moment, whereas this patient was actually under treatment for slight deafness before his brother's death. The same may be said for sudden deafness which sometimes comes on without any apparent cause. Then we come to consider chronic inflammation of the internal ear, concussion of the labyrinth from artillery practice. Acccording to Burnett: "A continual recurrence of a loud sound of an unpleasant character, causes hyperæmia of the ultimate nerve fibres of the cochlea. The deafness comes on, as a rule, gradually. Hyperæmia of the labyrinth often follows tympanic disease, as there is a close connection between the vascular structures of the tympanum and labyrinth." After artillery practice the tympanum, I think, is first involved, and subsequently the labyrinth. The hyperæmia of the labyrinth is often only temporary, and accounts for the cases where leeching and blistering freely behind the ear in the first stage of the disease, at once relieves the deafness. Of disease of the cochlea, "the prominent symptoms are, great impairment of hearing, the inability to hear certain tones, and the production of false ones, with tinnitus aurium. Artillerymen and boiler makers are liable to this form of disease, and they may effectually protect their ears from the destructive hyperæmia caused by concussion by plugging the ears with cotton-wool." A similar preventive measure I have already recommended for bathing. Therefore if loud noise had produced such irritation, it would have been highly beneficial to select a quiet residence for him, with a view of keeping him out of all noise, just as it is often necessary to protect the eyes from light. It was most important to know whether the disease of the labyrinth was due entirely to this concussion, or was it partly syphilitic or wholly due to syphilis? The very same symptoms as he had are common in boiler-makers, and those who are frequently exposed to shocks of concussion from the continuous clicking of telegraphic instruments, &c., &c.

Disease of the internal ear from syphilis is extremely rare. Burnett says: "The symptoms are sudden deafness accompanied sometimes by paralysis of other parts of the body and by vertigo, nausea, and unsteadiness of gait, and tinnitus aurium."

I consulted my colleague, Mr. James Lane, who was decidedly of opinion that this deafness *was* due to syphilis. We put him on very large doses of iodide of potassium (the only drug I have found of any service in these cases), a mode of treatment for intra-cranial syphilis which we owe in a great measure to Dr. Broadbent. I am sorry to say no improvement took place in this case.

Very serious events may take place from what, at first sight, seems to be only a rupture in the drum-head. The nature of the accident generally points out to us the likelihood of permanent deafness from further mischief in the internal ear. It must be remembered that from a simple rupture a chronic discharge may be set up, conducive to all kinds of complications, even to pyæmia, as in Dr. Handfield Jones's case, or as in the four cases of death from cerebral abscess I have mentioned.

Perforations from injury, on the whole, do better than those caused by disease, because I believe they are better treated. A man who has a blow on the head naturally says to himself, "My head feels rather queer, I will go and see the doctor;" whereas, after, may be, a long case of scarlet fever, people have had enough of the medical attendant, and if a discharge from the ear remains behind, it is generally left for a time at any rate to run its own course, the patient, or the patient's parents, having a strong conviction that the discharge will be grown out of! This is well shown in the actual recoveries, that is, in the cases where the perforation has closed and the hearing completely restored. Invariably in these the patient has been seen soon, and in no case of mine has complete restoration taken place where the discharge has been allowed to run its course for some years, although a few such instances are on record.

Forty-eight patients have been cured.

From diseases I find 26 perforations cured out of 526, or nearly 1 out of 21; from accident, 22 out of 92, nearly 1 in 4; taking box on the ears, I find 5 out of 10 cured, or 1 in 2. All these cases were seen early and a cure effected. This may seem a small percentage at first sight, but it must be understood that I have not yet mentioned the patients relieved; many cases where the hearing has been almost restored, but the perforation has not closed. Others, again, where it has closed, but the hearing has not been perfect; others, where the discharge has been overcome but still a perforation remaining with only slight deafness; and another class, where a perforation has been left and the assistance rendered to hearing has been most marked by the use of cotton-wool, or other artificial means. I mentioned previously 58 incurable cases, that is, those in whom the hearing was altogether lost, and no improvement took place from treatment; adding this number to the 48 cured it leaves 512 cases improved by treatment. In a great number of these the hearing has been restored, but a cure in every sense has not taken place. I have not even thought it fair to take those patients, not a small number, who have the satisfaction of hearing perfectly well, losing all discharge, and who consider themselves cured, but have a perforation left, and where there is an opening into the tympanum a discharge is likely at any time to return, together with further trouble.

I have analysed these 500 cases with great care, and I believe the averages arrived at are correct. Be it remembered that these are all picked cases of satisfactory history. I have treated thousands of perforations, most of them of no value whatever, for no history could be obtained. It is a common occurrence in hospital practice to get a patient like this: "Have you ever had a discharge from your ear?" "Don't know." "Have you ever had scarlet fever or measles?" "Don't know." "Tell me, have you ever had a cold?" "Don't know." "How old are you?" "Don't know." They are perfectly contented with them-

selves, ignorance seems to be bliss. The other day, asking a woman all these questions, and failing to get any satisfactory answer, in despair I said, "Well, then, what is your name?" She was equal to the occasion, she immediately replied, "Really, Sir, for the moment I've forgot!" In a great many instances of mastoid abscess in a large number of aural polypi, I have been unable to trace the origin of the disease, and so they have not been recorded.

There is an old proverb, "first catch your hare,' and so I would say, first find out your perforation and then treat it. A hole in the drum-head is often left undiscovered for months, and then, as I have shown, it is generally incurable. If doctors would only learn to use the Politzer air-bag a little more and the syringe a little less frequently, deafness would not be so common, and our results would be more satisfactory. For by means of Politzer's process, air is, as a rule, easily passed through the Eustachian tube, and of course if we get the characteristic whistle sound, it is unmistakable, a perforation is there. The same may be said if water, in syringing the ear, passes through into the nose—the fluid has passed through an aperture in the drum-head. By looking through the speculum a small perforation may be overlooked, especially if it occurs in the anterior and inferior portion of the membrane. I have attempted to show that perforations of the membrana tympani, if treated early, are readily curable. I have purposely, as much as possible, avoided reference to treatment, for that is easily learnt; neither have I time to speak of aids to hearing, such as artificial drum-heads, the audiphone, and trumpets—all useful instruments in various cases where the power of conveying sound to the brain has been, perhaps, thus partially lost. The analysis I have given teaches us this important lesson: By a correct diagnosis in the first instance, combined with an early and careful treatment, many people, now obliged to resort to these instruments, might have been cured, lives might have been saved; and it would not be so common to meet those whose whole lives are a blank, for no sweet sound is ever heard!

[ERRATA.—There were one or two printer's errors in Mr. Field's "Analysis of 500 cases of Perforation of the Membrana Tympani," in our last number, which we hasten to correct: line 10, "evil-producing" should be read with a comma, not a hyphen, thus, "sources of evil, producing perforations, &c." Second column, line 3, there should be no stop after "way;" and in line 21, same column, "membranous," should read, "membrana."]

SOME REMARKS UPON THE RECENT SMALL POX EPIDEMIC IN THE RATHDOWN UNION INFIRMARY.

By CHARLES CRAWFORD MAYNE, M.B., M.Ch., Univ. Dub.,
Surgeon to the Infirmary.

I DOUBT if any disease taxes more thoroughly the skill and ingenuity of the physician than that which is the subject of these remarks. He has to take into consideration not only the difficulties that may arise with regard to its treatment as far as "the patient" is concerned, but also those that may arise with regard to its successful prevention as far as "others" are concerned, prevention rendered all the more difficult by inability to adopt proper sanitary precautions, such as isolation, disinfection, ventilation, and last, but not least, re-vaccination.

Small-pox was, of course, met with in the recent epidemic, in all its varieties, from the milder forms tending to complete convalescence, to the graver forms accompanied with all its complications, and ending too often, alas, in death.

Of the discrete variety of the disease I have little to remark. It struck me however as peculiar, the tendency there was to the eruption crowding over parts of the body, where an injury had been recently received, or to its assuming the form of complete rings round the body or legs, produced by constriction of strings, or so slight a cause as the pressure of too tight a garter. The confluent form of the disease was often complicated with purpura and laryngitis. I saw one or two cases of ophthalmia. We had high temperatures, secondary fever, and occasionally a peculiar eruption, which for want of a better name I called a lead-coloured eruption, from which I never saw a patient recover. Deep seated pustules in palms of hands and soles of feet caused severe neuralgic pains. We met a few cases of violent delirium calling for restraint, a symptom by the way of favourable character as far as this epidemic was concerned. When either from some peculiarity of constitution (idiosyncrasy) or from, I am rather more inclined to suspect, the modifying influence of vaccination, a patient exposed to contagion, does not develop the disease with eruption as true small-pox, but has pain in the back, nausea, and pyrexia, all the symptoms in fact which other members of family or community in which the patient moved prior to developing the ordinary form of disease have suffered from, this is called small-pox fever, and this would appear to throw light upon the duration of the disease. These cases were well in about eight days like the other exanthemata; the continuance of fever in uncomplicated cases appearing to be due to either the irritation of the pustules or absorption of their contents.

Purpuric Fever or Hæmorrhagic Fever.—A patient, as in the foregoing case, precisely similarly circumstanced with regard to contagion, takes ill with all the symptoms that usually usher in the disease, and yet, instead of small-pox, the physician is called upon to treat purpura, in one of its many varieties. These cases as a general rule were protected by vaccination, and in one instance re-vaccination had been performed. Purpura, combined with small-pox, was met with in all proportions, from tiny blood-specks to be distinguished with difficulty, unattended with hæmorrhage, and therefore of little importance, to effusion of blood over parts of the body, entire limbs being thus occupied, the blood, absolutely refusing to continue in its vessels, deviated from its proper channel, by, it may be, some misdirected nervous influence, or so impoverished or defibrinated that it steals drop by drop from life's current, accumulating in deadly patches, to be most frequently observed in the groin and axilla. I have seen bleeding from the mouth, nose, bowels, kidneys, and uterus, and even the conjunctiva distended with blood, the eruption full of bloody fluid and bullæ of blood scattered over the body, and yet recovery. These cases of recovery I need hardly say were of rare occurrence; preternatural clearness of intellect usually accompanied this form of the disease, the mind remaining unclouded to the last. The great majority of females were menstruating when admitted, even when purpura could not be distinguished, the uterus seeming to sympathise with the disease.

Laryngitis existed in many cases, but I doubt if it averaged as high a percentage as in the epidemic of 1871, nor did the disease run as severe a course as a general rule.

Ophthalmia. — The occurrence of this complication must be less frequent than it used to be, I never saw an eye lost with this disease, and only upon two or three occasions have I seen the eye seriously attacked. The number of blind people we used to see pock-marked, must be an evidence of how frequently the eye was attacked, unless we base our arguments upon reasoning as absurd as the following:—"That blind people were particularly susceptible of the disease." Does vaccination protect the eye by modifying the disease? I think so. Eyes were lost in the old days of "inoculation," or during that period in which we must believe the great majority were unvaccinated.

Abscess occurred as a result of the disease. I saw one case in which the entire scalp was engaged. In another case an abscess formed slowly over the scapula, with exfoliation of a small portion of its spine. In a third case,

an abscess formed in the ear, only recognised when it discharged, causing temporary deafness.

Boils were very troublesome as a consequence of this disease, causing delay in convalescence, but otherwise of little importance.

Pleurisy supervened upon one case, but gave way quickly to the usual treatment. Patient discharged quite convalescent. And lastly, one case of sudden death took place in a child of two years, the effect of sudden muscular exertion, child falling back dead after vain attempts to grasp at toy kindly offered to it. This unhappy result was probably due to deterioration of muscular fibre of heart.

I would now draw attention to the following table of statistics—

——	Men.	Women.	Children	Total.
Number treated who were vaccinated . . .	46	46	20	112
Deaths in above . .	4	5	4	13
Discharged cured . .	42	41	16	99
Number treated who were not vaccinated or were doubtful . . .	14	3	16	33
Deaths in above . .	12	1	6	19
Discharged cured . .	2	2	10	14

In 112 cases that were vaccinated, only 13 deaths, or at the rate of 11½ per cent.; but in 33 cases that were not vaccinated, 19 deaths, or at the rate of 57½ per cent.

My object in giving foregoing statistics is to inquire, Does vaccination either modify or prevent small-pox?

I believe that small-pox is a disease that is *quite preventible*, and I will go further, and say, that it is the only one that is so.

Now, if vaccination fails to prevent small-pox, it may fairly be asked, how much of this failure is to be attributed to the vaccinator? For if, instead of giving a certificate of insusceptibility of vaccination, or being satisfied with an abortive attempt at it, the practitioner would only persistently vaccinate and not be discouraged by a few unsuccessful attempts, small-pox, like the plague of London, would only be a matter of historical interest.

Deputy Surgeon-General Moffatt never had a case of small-pox in his regiment in India when small-pox was raging there, he accounts for the immunity from the disease by careful vaccination and re-vaccination. He does not believe in insusceptibility of vaccination, but vaccinates persistently until the arm takes, and to this careful system of vaccination and re-vaccination adopted by the military authorities is to be attributed the following fact that, during the last ten years, embracing two epidemics of small-pox, only five cases of that disease occurred in the Dublin garrison.

A gentleman of an adjoining dispensary furnished one of his patients (a child) with a certificate of insusceptibility of vaccination, upon the family moving into another district, the medical officer of it (a very careful vaccinator, by the way), immediately successfully vaccinated the child, and returned the certificate of insusceptibility of vaccination together with certificate of successful vaccination to the gentleman who gave it, not a little to his astonishment, I believe.

Now a glance at the foregoing table, and a consideration of its rate of mortality or the remembrance of the length of time patients suffering from this disease must be separated from their families, or the loss, pecuniary or socially, they must incur, not to say one word about the physical suffering, the frequent hideous disfigurement and general loathsomeness of the disease, must convey to the most careless observer, an appreciation of the great benefit that Jenner's discovery has conferred upon suffering humanity.

I have no doubt that the Poor-law medical officers discharge the various duties imposed upon them with praiseworthy care, but I cannot help feeling that too much is expected from a class of gentlemen who are so inadequately remunerated.

Upon what pretext may I ask, are they paid less (*a*) for vaccinating *in Ireland than in England*. Or, why is not the distance that a medical officer has to travel to vaccinate in Ireland taken into account as in England? Are English miles longer and the roads harder to travel? And yet the vaccinator in England is paid 3s. for every case of successful vaccination he performs over two miles from his residence. Now I ask, how many vaccination stations in Ireland are not farther than that from the Poor-law medical officer's dwelling, and are not his dispensary stations, if he has more than one, often eight miles apart?

Is it an encouragement to the Irish medical officer to withhold from him the award for careful vaccination so often given to his brother practitioner in England? an award that gives so healthy a stimulus to vaccination. Is it harder to vaccinate a child in England than in Ireland?

I assert that it is easier, and I am prepared to prove it, for I have had experience of both systems. Would it be thought possible that a public vaccinator in Ireland was actually summoned by that most persuasive document, couched in such polite language, bearing signature of warden, or some member of dispensary committee, printed in red ink, presented with such tender solicitude for his comfort during his dinner hour, to visit a child, vaccinated just eight days previously, to find it in perfect health, and the arm simply the perfection of vaccination. And yet this has actually happened.

In conclusion, I am perfectly satisfied that, to stamp out small-pox and procure for vaccination those good results it can undoubtedly accomplish, primary and secondary vaccination must be insisted on. Primary vaccination ought to be from arm to arm. When practicable, four vaccine vesicles should be sought for, the vaccine mark should be as large as a fourpenny-piece, and pure lymph only should be used. In a word, vaccination should be extensive and satisfactory; and re-vaccination, after puberty, should be compulsory—for primary vaccination certainly modifies the disease, and secondary as certainly prevents it.

THE MEDICINE OF THE ANCIENTS.

By BERNARD KELLY, M.D.

ARETÆUS, OF CAPPADOCIA.

THIS physician, according to Leclerc, the erudite and accomplished author of the "Histoire de la Médicine," was a Pneumatist or Spiritualist, that is, one of a sect who maintained that diseases were owing to a derangement of the *spirit*—one of five elements—viz., the *hot*, *cold*, *humid*, and *dry*. The two first appertain to the *efficient causes;* the third and fourth to the *anatomical causes*. The other element, or that of *spirit*, originated with Democritus, the Stoic, who was styled the Father of the Pneumatic Sect. Atheneus, applying this system to medicine, held that the majority of diseases arose from a disturbance or shock to the spirit. "The pulse," said he, "is nothing else than a movement produced by a natural and voluntary dilatation of the spirit lodged in the arteries and heart, which spirit, moving spontaneously, moves also the heart and arteries at the same time."—(De Different. Puls., lib. iv., cap. 4. Galen).

According to Aretæus, there were two kinds of quinsies—the one due to an inflammation of the respiratory appa-

(*a*) Written before new Act.

ratus; the other, to an affection of the *spirit*, which is, itself, the cause of the disease. In the latter variety, he remarks, the air-passages, far from being swollen, or narrowed, are more patulous than in the healthy state, and, nevertheless, the suffocation and difficulty of breathing are greater than in the former—a fact which led to the supposition of the existence of an inflammation, deep-seated, and bordering on the heart and lungs. "It is the spirit," he says, "alone which suffers" in such cases. Aretæus maintained, in support of his spiritual doctrines, that the breath of a mad dog was fatal to those who respired it. "It is, therefore, not strange," he continues, "that the Athenians, who knew not the relation existing between the effects of certain poisons and those of certain pestilential diseases, imagined their ailments arose from the Peloponesians, with whom they were at war, having poisoned their wells."

Aretæus, doubtless, meant by the *spirit*, the *matter* of *respiration*, for he says in another place that *asthma* is *caused by cold*, or *humidity* of the *spirit*. In like manner *ileus* is produced by a *cold spirit*, which neither ascends nor descends. Scirrhus of the spleen is owing to a *thick, tenebrous spirit*. Tympanitic dropsy, which remains fixed, whether the patient reclines or stands, is due to a spirit; but that when this spirit changes to a vapour, or water, the tympanitis changes to an *ascites*. In order to cure peripneumony, we must, he says, draw to the surface the *humors*, the *heat*, and the *spirit* which oppress the lungs. He recommended the use of *milk*, *amidon*, and *alica* in phthisis, for the purpose of thickening the *blood* and *spirit*.

As already remarked, the Pneumatists or Spiritualists maintained that the title of elements properly belonged, not to *fire*, *air*, *earth*, and *water*, but rather to the properties they possessed—viz., *heat*, *cold*, *dryness*, and *humidity*, to which he added a fifth, that of *spirit*. Thus, *syncope*, according to Aretæus, arises from *cold* and *humidity*; *headache*, from *cold* and *dryness*; *vertigo*, from *cold* and *humidity*; *epilepsy* and *melancholy*, from *dryness*. In the *dropsy*, called *leucophlegmasia*, he recognised a *fluxion*, *cold* and *thick*, which moistens the whole body, and produced the same effects as do fogs on the earth and atmosphere. *Cœliac flux* is due to *coldness* of the *stomach* and *feebleness* of the *heat* which *digests* the *food*. *Leucorrhœa* of females is due to coldness of the womb, by which the *red* blood is changed into *white*. *Gout* also proceeds from *cold*; while *lepra*, or *elephantiasis* arises from *coldness* the most *intense*.

Unlike the dogmatic and empirical physicians, he very seldom speaks of bile, phlegm, and other humours as the efficient causes of disease. For him these constitute merely the material. Thus, "asthma is caused by coldness and humidity of the spirit, and thick, clammy humors constitute its matter."

Aretæus has left us four books on acute diseases; four on chronic, or long, in which he speaks separately, on one side, of the causes and signs; on the other, of their cure and treatment. Cælius Aurelianus, physician of the Methodist sect, who flourished in the second century, divided, in like manner, diseases into acute and chronic, or long. Like the Methodists, Aretæus gives special instructions respecting the manner in which the chamber of the patient ought to face, and be arranged in certain diseases; what air he should breathe; the kind of bed he should occupy; the quality and quantity of bed-clothing he should require. Although, unlike the Methodists, he says nothing about *flux* and *recrement*. He imitated the Methodists in the mode of exercise he prescribed his patients during convalescence—viz., walking, riding, singing aloud, casting the quoit and certain heavy implements, which he called *halteres*. He also enjoined a gesticulation of the hands (cheironomia), already mentioned in the diet of Hippocrates. All these means had been employed by the Methodists. Aretæus went further than they: he recommended the rough exercise of pugilists and gymnasts to such as were affected with vertigo. He, moreover, imitated the Methodists by his use of external applications, such as fomentations, cataplasms, ointments, &c. He employed purgatives, against which the Methodists, especially Thesalus and Soranus, were so strenuously opposed. The composition, known as *hiera picra*, is one of which he made extensive use. He administered simple purgatives, as elaterium, cnicus hellabore, &c. He differed also from the Methodists in the employment of acrid and irritating injections in certain cases. He also used castoreum and soporific medicines, as the poppy and opium—a practice which was entirely discountenanced by the Methodists; but with this important precaution: "It is necessary," said he, "sometimes to give narcotic medicines to those having a peripneumonia, and worn out by a long-continued insomnia, lest they should lapse into phrensy, and in order to assuage their disease and their restlessness. But we should never give medicines of this kind when the patients are threatened with suffocation from fluxion, or when they are at the point of death, because we thereby expose ourselves to the public accusation of having killed them." Great and immortal Aretæus!

He bled differently to the Methodists. He remembered that in apoplexy a copious venesection killed, whereas a small one was of no benefit. His practice was to bleed moderately, and repeat, if necessary, the venesection. In quinsy he was wont to bleed to syncope. In hæmatemesis he always recommended bleeding, whether it arose from a rupture of a vessel, or from its erosion by the acridity of the blood; or from thinness of the vessel's walls; or from plethora. He repeated the depletion from the same orifice for several successive days, provided the patient was not too weak. "Why," demanded he, in reproof of the current practice of his time, "do you open a vein near the fingers rather than at the bend of the elbow, since at the latter point the vein is larger and more conveniently disposed for the evacuation of the blood?" In continued fever (*causus*) he bled repeatedly for several days, because he believed it arose from a phlegmon or inflammation of the *vena cana*. In nephralgia from the passage of calculi and in acute nephritis he bled copiously. He opened a vein of the forehead in headache; also the veins of the nares by means of instruments which he called *cateiadion* and *storynea*. These failing, he employed a goose-quill pointed, which he pushed as far as the ethnoid bone. In elephantiasis he bled the same day from both arms and both legs.

He also employed emetics of narcissus and white hellebore, which, he says, acts in the same way as the disease known as cholera. White hellebore was a favourite remedy with Aretæus. He employed it, not because it produced distressing nausea and vomiting, for sailing in a ship, as he stated, induced the same effects, but on account of its peculiar virtue, which one cannot sufficiently admire; and although it purges very gently in some cases, it is still not the less effectual in curing the disease. Moreover, in chronic affections, when all other remedies fail, this alone succeeds. In a word, white hellebore has relation to fire. What fire does in burning white hellebore does, yet more powerfully, in traversing the entire system. It renders the respiration free for those who can only breathe with difficulty. It gives a good colour to the pallid, and *embonpoint* to the lean. ("Histoire de la Medicine," p. 513.)

The Methodists and the majority of the ancient physicians employed medicines which they called *metasyncritic*, for the purpose, as they considered, of drawing from the centre to the circumference. To this end they used mustard and a plant called *thapsia*. Aretæus, in addition to these, employed cantharides as a vesicatory. Archigenes, who lived about the time of Aretæus (first century), and who belonged to the same sect (Spiritualist), employed this remedy against the itch and lepra; and also used it internally as a diuretic. Hippocrates also used it internally, but says nothing of it as a vesicatory. Aretæus treated epilepsy and headaches with friction of cantharides. "We have used," says Archigenes, quoted by

..., "a cataplasm, into the composition of which ...charides enter with excellent effect, provided that the small ulcers which it excites remain open and run a long time; but we should protect the vesicle (*bladder?*) by the internal and external use of milk."

Aretæus speaks of a dropsy which escaped the notice of his contemporaries and predecessors. "There is a species of dropsy," he says, "caused by a great number of bladders filled with water, which is located in the same region usually occupied by *ascites*. Each of these vesicles is quite full; and if the lower belly be punctured with an instrument suited to the operation, the first that is met with discharges its water, but collapses immediately; and if we desire to withdraw more water we must push the instrument further in. Some people," he adds, "affirm that these bladders come from the intestines, but not having observed the fact I can say nothing about it." ("Hist. de la Med.," p. 514.) Our author evidently alludes in his account of the dropsy in question, either to multilocular cysts of the ovaries, or to hydatids affecting the uterus, ovaries, or liver. Aretæus was accustomed to give an anatomical sketch of the parts of the body whose diseases he was about to describe. He employed cups (cucurbitulis), as he speaks of cupping, leaching, &c., in cholera, apoplexy, epilepsy, hysteria, and so on. Thermison, who flourished a little before Aretæus, was the first, it seems, to use leeches. It is to this physician, doubtless, Juvenal alludes, although not in very complimentary terms, as we may judge from the following couplet:—

"Promtius expediam, quot amaverit Hippia moschos;
Quot Themison ægros autumno acciderit uno."

Celsus and Galen, who came after them, make no mention, however, of this fact. Aretæus employed them (leeches) especially in three diseases—in cardiac affection, in satyriasis, and inflammation of the liver. He was accustomed also to apply cupping glasses to the *bites* as soon as the leeches had fallen off. He praises in the highest terms the efficacy of wine in sickness. Alluding to this his commentator (Petrus Petitus) judiciously remarks:—"Id (vinum) ideo cum cibo aquaque mixtum alias dari præcipit, eam medicocritatem interim secutus, ut neque æger inedia consumatur, negue cibi copia opprimatur."

As an appropriate appendage to the foregoing sketch of this great master of our art, I perhaps can do no better than translate a few passages from the Latin version of his works (for Aretæus being an inhabitant, if not a native, of Cappadocia, wrote in Greek), and which may serve, at the same time, to illustrate his style and the consummate manner in which he handled his subjects.

Epilepsia seu morbus Comitialis. "And these are the accidents which take place towards the close of an attack. But when the symptoms of the disease have entered on a remission, the urine is incontinentdly voided, the bowels are relaxed, and in some cases, on account of the constriction and compression of its proper vessels, by which a certain painful irritation is induced, a discharge of semen takes place."

Icterus.—"Hence, in jaundice, the natural appearance (corporis species) of the body becomes discoloured with bile. The fæces, too, are whitish, resembling clay, not presenting the slightest tinge of bile, since there is a complete absence of the afflux of this humor. Hence, too, the bowels are *dry* (constipated), not being moistened and stimulated by the bile."

Dysuria.—"The anus and bladder lie close to each other; wherefore, in an inflammation of the rectum, the bladder is affected with a difficulty of urine, and when the bladder is the seat of the disease, no alvine evacuation takes place, although the intestine may not be *dry* (constipated).

Paralysis.—"Consequently, if any principle (*principium aliquod*) below the head be affected, as the membrane of the spinal cord, both *the parts that are called by the same name*, and even those that are continuous with them, are relaxed (paralysed); the *right*, if the nerves of the right side be injured; the *left*, if those of the left. But, if the procatarctic cause be seated in the head, the right nerves being affected, the *left* parts are *relaxed*; the *left* similarly suffering, the right side is paralysed."

Cholera.—"At the outset, these (*i.e.*, the vomiting and purging) take place easily, and without pain; subsequently, with torminia and tenesmus. Should the disease go from bad to worse, the griping becomes aggravated, and there ensue prostration of the spirit, relaxation of the members, anxiety, loss of appetite. . . . Cramps (*nervorum distentiones*) supervene; the muscles of the legs and arms are contracted; the fingers become incurvated; vertigo and hiccup ensue; a death-like coldness comes on; the extreme parts, especially, become algid; and the whole body grows cold and shrivelled. . . . The urine is voided in small quantity, either because the bladder is pressed by the convulsions (cramps), or because there is very little urine secreted, by reason of the derivation of the humours to the intestines. The voice fails (aphonia): the pulse grows small and very frequent, as in *syncope*. There are constant and ineffectual attempts at vomiting; there is a desire of often going to stool, as in tenesmus; it is *dry*, however, nothing being excreted. A death, most painful and miserable, by reason of the convulsions (cramps), straining, and empty retching, closes the scene. The affection is especially prevalent in summer; next to this, in autumn; very rare in spring; but, rarest of all, in winter. As to age, both youths and those who have reached maturity, are equally obnoxious to the disease; old persons least of all, boys most so, but without the danger of death."

Clinical Records.

CASES SEEN AT THE METROPOLITAN FREE HOSPITAL.

By C. R. DRYSDALE, M.D., F.R.C.S.,
Senior Physician to the Hospital, and Physician to the Rescue Society's Lock Hospital.

THE following case of cerebral syphilis is one of a number observed by Dr. Drysdale during the last twenty years, in hospital and private practice. That there are diseases of the encephalon produced by syphilis is almost solely the acquisition of the last 25 years. Before that date surgical writers, who occupied themselves with syphilitic questions do not seem, as a rule, to have recognised that the poison of syphilis could affect the nerve tissues to any extent. Observations of exostosis, indeed, of the bones of the skull accompanied by hemiplegia, had been received as trustworthy in the literature of syphilis; but it was not until the writings of Gros and Lancereaux, Diday and Fournier in France, conjoined with those of Jackson, Broadbent, and others in England, with Heubner, Virchow, and Bidenkap in Germany, appeared, and threw a flood of light on the subject, that cerebral syphilis has taken its true place in pathology.

Case of Cerebral Syphilis.

Elizabeth Greening, æt. 32, widow, was admitted December 16, 1879, into the Metropolitan Free Hospital, suffering from paralysis of muscles of right eye, almost complete amaurosis (could just count fingers), and anæsthesia of ophthalmic division of 5th nerve of same side. Had been an out-patient for a fortnight. A week before she came as out-patient she found a mist coming before right eye, and the ptosis came on suddenly several days before she came as out-patient.

History.—Perfectly healthy till her marriage 13 years ago. Her husband died five years ago. Has had six children and one miscarriage. 1st child, 7 months child, died; 2nd, lived 4 days; 3rd, 16 weeks; 4th, miscarriage; 5th, alive, weakly, 9 years old; 6th, died early from fits; 7th, born dead. Her husband had been ill shortly before her marriage—she did not know with what, but suffered from sore throat, and lost nearly all his hair after marriage. After birth of first

child husband was in St. Bartholomew's Hospital for 16 weeks, for what appears to have been hemiplegia of gradual invasion, and never thoroughly recovered use of leg or arm. Patient lost her health after birth of second child, was treated at St. Bartholomew's for two months for sore throat and abscess in breast. For next two years attended at St. Bartholomew's off and on for sore throat and loss of voice. Appears to have had good health till birth of seventh child. After death of husband suffered again for some months with sore throat. Two years ago she was suddenly seized with giddiness in the street and fell, cutting right eyebrow severely, attended Metropolitan Free Hospital for a month as out-patient, where she had drops put into her eye every other morning. On this occasion she says she completely lost sight of eye for a week, and had no feeling over or round the eye (ophth. division of 5th) for some time. From this time she suffered intermittently from severe pains in the head, principally in the frontal and occipital regions, which were much more intense at night. For a month before coming as out-patient she suffered more severely from these pains.

Treatment.—The patient was treated with iodide of potassium (thirty grains three times a day) ever since admission. In addition ung. hyd. fort., 3j. was ordered to be rubbed in once a day on inside of thighs, but had to be discontinued on fifth day, owing to extensive salivation.

The anæsthesia rapidly disappeared, and was almost gone one week after admission.

The ptosis gradually became less (January 7th).

The pupils were all through semi-dilated and unaffected by light, but seemed then to be *very* slightly affected by atropia.

Muscles were beginning to act; amaurosis has been complete about a fortnight.

Pain in head (with nightly exacerbations) constant.

Patient lay in a drowsy condition, never complaining, but seldom slept, and dreaded being moved, bowels confined. Temperature normal throughout. The sight of left eye was, and had been, sufficiently good to read ordinary newspaper print at about 8 inches.

Patient denies ever having had any skin disease, but said her husband had had some disease before her marriage, which aroused her suspicion, and about which she questioned his landlady, but without being able to find out much. She left hospital in an incurable and almost hopeless condition. The treatment in this case has not been commenced early enough in the disease to prevent irreparable damage to the encephalon.

Progressive Muscular Atrophy.

Emma Pritchard, æt. 38, silk winder, married five years, four children, last child two years ago. Two children died (premature births). Six years ago suffered from swelling and aching of all the joints of both hands, and of the wrists, attributed to cold, and from "shooting" pain of these joints on movement; similar pain on moving elbows and shoulder-joints, the pain from these seemed to run down the arm to the fingers. This affection of the joints continued two months, during which time she kept her bed; on leaving it she noticed wasting of hands and feet.

Hands have now a claw-like appearance, the first sets of phalanges are extended, the two terminal sets flexed. The muscles of ball of thumb, hypothenar eminence, and all the other muscles in the hand appear completely atrophied. The muscles of arm seem intact. The deltoids are a little wasted. Tremors, increased by excitement, of extensors of fingers, and of ball of thumb are seen, and have been noticed for two years. Can flex fingers, but wrist only imperfectly; cannot extend two terminal phalanges. Can extend, flex, abduct, adduct imperfectly, thumbs, but cannot oppose at all. Has shooting pains in joints at times. Muscles in the forearm are wasted.

Feet.—Muscles in sole of foot appear completely wasted, and those in leg are less completely atrophied. Cannot extend toes, which are in flexed condition. The scaleni are wasted, and the trapezius stands out.

The atrophy appears slightly less complete on right side of the body.

The face appears emaciated, but patient can execute all the movements of expression.

Muscles in other parts do not show any distinct atrophy.

Is still able to follow occupation of silk winding.

The cause of this deplorable wasting of the muscles in so young a woman, appears to have been cold and excessive labour. She had, in following out her occupation, often had to carry great weights to and fro to her employers, and six years ago, when the malady first appeared, she was exposed for a long time to excessive cold in a rigorous winter. The prognosis was evidently gloomy in the extreme, and the fatal termination could not be very long postponed, as the muscles of respiration were gradually becoming affected. Arsenic, cod-oil, and iron were given.

Translations.

THE PHILOSOPHY OF SLEEP AND DREAMS.

By M. DELBOEUF.

Translated from the *Revue Philosophique*.

By EDWIN JACKSON, B.A., M.R.C.S.,

Manchester.

PART I.

CRITICAL SKETCH OF SOME RECENT WORKS.

I.

FROM the laughing Iona, the cradle of the sad Heraclitus, to the stormy Baltic, which gave birth to the sombre Schopenhauer, in every age and in every clime, if there is one subject which philosophers have worked out with feelings of satisfaction, it is that of the miseries of man. In their turns, religious writers, Pascals and Bossuets, while extolling the grandeur of the human soul, never fail to set forth its meanness also. It would seem, then, impossible to add new features to the dreary picture of our weakness and our nothingness. And yet in it we forget to set forth a full third of our existence. Every day we are, so to speak, snatched away from ourselves by a fantastic, strange, and capricious spirit, which takes a grim pleasure in blending contraries—good and evil, vice and virtue. At certain hours of the day the best of men will commit without remorse the most abominable of crimes; he will become a thief, a murderer, a libertine, a perjurer; the pure young bride will abandon herself to the most unseemly actions; the modest nun will allow the most filthy words to escape her lips; the pious priest, carried away by passion or by fancy, will shrink from no sacrilege. When the besetment has ended, and we regain possession of ourselves, we should not dare to relate to others, or at times even to revolve in our own memories, what we have dreamt about. We ask ourselves anxiously if we do not carry in the secret places of our souls some horrible germ which, at some time or another, may lead us into crime. We curse that unknown power which, taking possession of our mind, takes away from it what is good, to replace it by what is worse. But, on the other hand, the action of sleep is quite as frequently kindly and comforting; it carries us back for a few moments into the midst of those whom we have loved and lost; it makes the sick man forget his illness, the poor man his poverty; it restores activity to the paralytic, hearing to the deaf, sight to the blind, liberty to the prisoner, the joys of a first love to the poor abandoned girl: illusions only too short, and which serve only to render the bitter reality more bitter still!

The magic wand of dreams transforms the most miserable hovel into a charming palace; it unlooses the tongue of the stammerer, and inspires him with an enchanting eloquence; it enables the timid to brave the most terrible dangers; its gives to the scholar the key to the most mysterious phenomena; it goes so far as to give to our clumsy, grovel-

drous wings, which carry it without effort e space.

y wonder, then, that in every age men should have ced to dreams a supernatural character? They are ded as messengers sent by a higher power; messengers e or false, according as they are well or evil-disposed owards us. They reveal the secrets of the future, and anyone who can understand their language may, without difficulty, make out their promises or their threats. And if, no longer concerning ourselves with the opinions of the vulgar, we ask men of science, we hear them propound at the very beginning of the contest against superstition a surprising theory: dreams, far from being the creations of gods, have, on the contrary, been the creators of them; our mind, which in sleep saw phantoms accomplish extraordinary things, attributed to them a real existence, and endowed them with a terrible power, and thus it is that heaven was peopled. (*a*) Or again, it is said that the images of those no longer with us, coming to haunt us in the silence of the night, have inspired belief in a future life, and the souls of kings and of mighty chieftains have been insensibly raised to the rank of divine spirits, holding in their hands the fate of the living. Thus, these strange creations of weariness, and of the night, which in our waking hours inspire us with scorn or with pity, with laughter or with disgust, have given birth to religious ideas, and that religious feeling which, according to some philosophers, is perhaps, the sole distinguishing characteristic by which man is raised above the beasts, has no other origin. Religion is the daughter of darkness; science the daughter of day-light! Surely this difference in origin is in itself sufficient to account for their incessant conflicts, and their irreconcilable antagonism!

II.

The importance which has always been attached to dreams would lead us to expect that in early ages men would have commenced the study of them, and that we should ere now have arrived at certain exact and definite notions respecting their nature and their causes. This is by no means the case. We cannot recall any works of the ancients on this subject, with the exception of some masterly pages left by Aristotle; and as regards modern times, Maudsley (*b*) has quite recently written the following lines: "Dreams have been a neglected study; nevertheless it is a study which is full of promise of abundant fruit when it shall be earnestly undertaken in a painstaking and methodical way by well-trained and competent observers. To physicians of all men is it likely that they will prove full of instruction.

As to the actual state of the science of sleep, I am not in a position to be able rightly to estimate it. I will content myself with quoting the words of Vierordt, whose ability is unquestioned (*c*): "As to propounding a physiological theory of sleep, we cannot think of it. Why is there this general need of a periodic reduction or of a partial suspension of our physical and mental activity? What are the conditions—undoubtedly very numerous—bodily as well as mental, which cause physiological sleep; and in due course during sleep produce our awaking? What, in short, in quantity and quality are the determinate forms under which the functions of the sleeper manifest themselves? All these are questions which it is impossible to answer."

It is not that there have not, for some time at least, appeared any works on sleep and dreams. Not to speak of the classic works of Alfred Maury and Albert Lorraine, and confining myself to the last two years, I will describe a little work of Serge Serguèyeff (*d*); a work of M. Grote, written in Russ (*e*); a volume of three hundred pages by Heinrich Spitta, teacher in the University of Tübingen (*f*); a still more voluminous work by Paul Radestock (*g*); a pamphlet by C. Binz (*a*); another by Paul Dupuy, Professor in the Faculty of Medicine at Bordeaux (*b*); I have certainly not exhausted the list, and perhaps I shall omit some of the best. I should have further to mention some treatises on physiology, on pathology, &c., in which sleep is the subject of some elaborate and lengthy chapters, which might well form a separate volume. Thus, Maudsley, in the work already mentioned, devotes to it nearly a hundred pages, and Prof Stricker, of the University of Vienna, has followed up his "*Lessons on General and Experimental Pathology*," (*c*) with a sort of course of psychology, which occupies no less than eleven chapters, and which, while it has for its object the explanation of mental diseases, contains a number of new and original views on the nature of dreams.

I shall not pause very long over the original but not very important work of M. Serguèyeff. The author begins by asserting that sleep is an "essentially vegetative function" (*une function essentiellement végétative*), for it is necessary to everything which has life. We have then to ascertain three things: (1) the food, the object of waking and of sleep, (2) the organ, (3) the mechanism.

The food is not necessarily a tangible and ponderable matter; there is nothing to prevent our conjecturing that the object of sleep is of an ethereal form, sthenic or dynamic. What M. Serguèyeff means by this I cannot understand.

As to the organ of sleep, it would seem probable that it is the great sympathetic system; for on the one hand we do not know the seat of this function, and on the other we are ignorant of the function of this system. The conclusion is by no means self-evident; but the author is not satisfied with this simple logical argument, and rightly so. He reminds us that section of the sympathetic gives rise to phenomena of heat, which cannot be attributed to modifications thus introduced into the circulation of the blood, and for which an explanation has not yet been found; then the increase of heat is easily explained by the arrest of a vegetative and centripetal movement; during the waking moments there is an accumulation of force, during sleep the excess of it is discharged. This is just the reverse of what is commonly believed. I am not a physiologist, and I cannot discuss the deductions of M. Serguèyeff, but I should just like to ascertain—and this is what all along I was expecting to meet with as the final argument,—to what extent animals whose great sympathetic has been cut lose their sleep; if, for example, that dog, in which after eighteen months the increase of heat was still perceptible, had not during the whole time slept pretty much as usual.

The, in my opinion, barren attempt of M. Serguèyeff seems to me calculated to show us in what profound obscurity the physiological problem is buried. This writer has certainly taken his subject to heart; he has given himself up to numerous researches, and gifted as he is with an ingenious turn of mind, he has aimed at leaving the beaten tracks; for all these reasons, whatever I may think of the result of his efforts, of the efforts themselves I can only speak with praise.

I have not read M. Binz's little work; I have seen an account of it in the *Berliner Klinische Wochenschrift*. M. Böhm, in the *Philosophische Monatshefte*, speaks very favourably of it. Starting from the fact that opium, hachish, ether, &c., produce states analagous to dreaming and sleep, M. Binz concludes that these phenomena are of a pathological nature, and proceed from some disturbance of the psychical activity. It is to me somewhat difficult to understand how we can set down as a pathological state, and attribute to any disturbance whatever, a phenomenon so universal, so constant, so beneficial as natural sleep, accompanied or not by dreams. But I stop here for fear of entirely misrepresenting M. Binz's idea.

I have read the little work of M. Dupuy; I have seen in it the interesting record of some of those phenomena to which M. Maury has given the name of hypnagogic hallucinations, and a criticism of some theories of sleep. This latter portion is very superficial, but it is true it makes no pretensions to anything more.

I will say nothing of the work of M. N. Grote; I know only its conclusions, formulated in this very Review in

(*a*) Lucretius: De Rerum Natura.
(*b*) "The Pathology of Mind," (1879) p. 49.
(*c*) "Grundriss der Physiologie des Menschen," 5e edit., Pp. 653. Tübingen, 1877.
(*d*) "Le sommeil et le Systeme nerveux, préparation à l'étude de la veille et du sommeil." Genève, 1877.
(*e*) "Les rêves, comme objet d'analyse scientifique." Kiev, 1878.
(*f*) "Die Schlaf und Traumzustände der menschlichen Seele, &c." Tübingen, 1878.
(*g*) "Schlaf und Traum. ein physiologisch-psychologische Untersuchung." Leipsig, 1879.

(*a*) "Ueber den Traum." Bonn, 1878.
(*b*) "E'tude psycho-physiologique sur le sommeil." Bordeaux, 1879.
(*c*) "Vorlesungen über allgemeine und experimentalle Pathologie." Lessons 21 to 31. Vienna, 1879.

the November No., 1878, by M. A. H.; they are sufficiently interesting to justify me in reproducing them: "Subjective sensorial excitements are taken for realities because of the absence of control over the senses and the intellect. The factors of dreams are principally reminiscences, habits, impressions received by the senses, and organic sensations, which accompany the vegetative process during sleep, and further "unconscious cerebration," or the automatic work of certain parts of the brain which are less fatigued or more excited, which unexpectedly furnish fantastic images, grotesque combinations of fragmentary representations mixed up haphazard, like the figures in a kaleidoscope. There is, however, always a more or less evident link between the ideas which follow one another, because sleep does not abolish the laws of association of ideas, and these continue to call them forth by resemblance or by contrast, or in conformity with the reciprocal relation of cause and effect, of means and end, exactly as this takes place in lunatics, in whom certain parts of the brain impose their activity upon consciousness, and monopolise it so completely that they obscure the objective sensorial impressions which might restore the psychical work to its proper path." This passage seems to me to express very well the actual state of our knowledge on the subject.

I should pass a similar opinion on the two substantial chapters in which Dr. Maudsley has treated of sleep and hypnotism. I should criticise the rather singular statement that ideas have "a natural tendency to combine and to arrange themselves into a kind of drama, even though they have no known associations and appear quite independent of, if not antagonistic to, one another." They would further have, according to Dr. Maudsley, "an actual constructive agency, whereby ideas are not brought together only, but new products are formed out of them." This is rather too bold an evasion of the difficulties relating to the dramatic and creative power of dreams; but we are often obliged, on such a subject as this, to be content with words, and Dr. Maudsley himself is not deceived by the involved explanations which he gives of the singular phenomena of recollections which dreams present: "Whatever the explanation," he says, "the fact is indisputable."

A particularly valuable summary is that in which he enumerates the conditions which determine the origin and character of dreams; he classes them under six heads: 1. Character, and precedent mental experience. 2. Impressions on a special sense. 3. The state of the muscular sensibility. 4. Organic or systemic impressions. 5. Conditions of cerebral circulation. 6. The state or tone of the nervous system.

Dr. Maudsley has treated of the states of sleep and dreaming only incidentally, and from the point of view of the analogy which they present with mental alienation; still, he has treated with great clearness several of the questions which they raise, and makes us feel the insufficiency of our knowledge of the subject.

M. Spitta has set himself the task of showing that the phenomena of reason, of dreams, and of hallucination are connected by numerous delicate gradations, that they pass somewhat into one another, and are subject to the same psychological laws. His work is written with a youthful and poetical dash somewhat prejudicial to that accuracy which we like to observe in a scientific treatise. At the moment when we are expecting a deduction, we come upon a highly-coloured and glowing description, which charms, it is true, but which certainly does not teach us much; and this kind of surprise is repeated too often. In spite of this pleasing fault, I would not pass upon this book so severe a judgment as does M. Böhm, in the above-mentioned review. We recognise in it considerable learning, some fine analysis, and some clever comments.

What, according to Spitta, is characteristic of profound sleep, is the absolute abolition of consciousness. When we dream, or are in a state of somnambulism, we possess consciousness, but not that self-consciousness which is the accompaniment of the waking state. It is this quality, unfortunately but too uncertain, which serves him in explaining how it is that dreams ordinarily are strange and incoherent, why they do not call forth astonishment in the sleeper, why, when they are vicious, they are not accompanied by shame or remorse. It is by the absence of self-consciousness that we explain the assurance and the confidence of the somnambulist in walking on the roof, the phenomena of ecstasy, and the doubling of personality, which makes us, for instance, in our dreams attribute to others our own thoughts.

There is another *deus ex machinâ* which, in Spitta's book, both plays quite as important a part; it is the *gemüth*, an expression difficult to translate.

The *gemüth* never sleeps. The *gemüth* is the greatest enemy of sleep, and when it takes possession of the mind there is no room for rest. Noise, light, activity, plans, nothing puts any obstacle in the way of sleep from the moment when the *gemüth* is unaffected; but if it is disturbed—as, for instance, when we are possessed with an idea that we ought to get up at a fixed time—our sleep is light, and a little suffices to interrupt it. A mother, deaf to all other sounds, is wakened by the least movement of her child. The dreams which impress themselves on our memory are those which have keenly excited our sensibility. Anxiety or an evil conscience keeps us awake, so great is the influence of the *gemüth* over our reason, which would attempt, but in vain, to call for sleep.

The dream is "the involuntary, but conscious, projecting of a series of pictures of the mind during sleep—an act which gives them, so far as the sleeper is concerned, an appearance of objective reality." The order and arrangement of the images obey the laws of association, and of reproduction of ideas, but not the laws of causality; the dream is illogical. As to the question put by Descartes—"By what sign can we distinguish the waking state from that of dreaming?"—M. Spitta declares it "imaginary and hypothetical." Perhaps one might venture to say that this is scarcely an answer.

In the waking state our world is also that of others. In sleep it is our own: centripetal activity meets with a stoppage; the formation of ideas is frequently interrupted, and as self-consciousness is not there to direct it, and the working out of external impressions by the intellect is naturally imperfect, if not null, we easily see why dreams are obscure, irregular, and wanting in correctness. It is even a matter for surprise that we do occasionally have logical dreams; these ought to be peculiar to those minds in which there is a habit formed of always arranging the thoughts systematically.

(*To be continued.*)

Department of Lunacy.

THE CATERHAM IMBECILE ASYLUM.

THE vast asylum at Caterham, of which the Annual Report has just been issued, contained on the 31st of December last 2,031 patients, 2,247 having been under care and treatment during the previous twelve months. Caterham, and its companion asylum at Leavesden, are the Sodom and Gomorrah of lunatic hospitals; their inhabitants are doomed to destruction, of which only a miserable remnant is permitted to escape. Of the 2,247 patients under treatment at the former last year, just 7 were discharged recovered. The work of the medical officers amidst such a hopeless mass of human *débris* must be peculiarly trying and disheartening, but it appears to be very successfully performed, for the health of the inmates was good, and the death-rate low last year, while no fatal accident nor suicide occurred. Dr. Adam, the medical superintendent, has very little doubt that a large number of merely old, feeble, and paralysed people have, by a too facile system, found admission to Caterham, and it may, he remarks, be worthy of consideration whether it would not be better in the future that all cases should in the first instance be admitted into the county asylum under the proper order and medical certificate, and thus be afforded all the protection which the Lunacy Acts confer.

BYSHIRE COUNTY LUNATIC ASYLUM.

nual Report of this important asylum, which has hed us, is rich in interesting matter, bearing not y on the sanitary and financial position of the establ ment, but on the moral and medical treatment of the patients. Some medical notes of much value are appended to it, among which we observe two remarkable cases in which severe cranial injuries were sustained without any prominent symptoms being observed during life. At the autopsy on a female epileptic patient, a hole half an-inch in diameter was discovered in the skull a little to the right of the foramen magnum. The internal table had been splintered, and the pieces ossified to the margin of the aperture. The dura mater was absent at the site of the injury, and the cerebellum rested on loose cellular tissue. On referring to the casualty records it was ascertained that three years before her death this patient had fallen in a fit, striking the back of her head on an iron hob, on the upper bar of a grate, and causing a small flesh wound, which healed rapidly without a bad system.

On July 3rd of last year a chronic maniac sustained a compound fracture of the skull by falling on a nail which projected from a piece of flooring under repair. He was picked up by his attendant, who found the board adhering to his head. The medical officer extracted the nail, which had entered the frontal bone, midway between the external angular process and the helix of the left ear, penetrating to a depth of five-eighths of an inch. The patient made but few complaints, and in the evening his pulse was quiet and full; not a symptom of meningitis followed. The wound healed rapidly, and in a few days he was as noisy, filthy, and mischievous as ever. He died three months afterwards of pulmonary disease, and at the post-mortem examination it was found that in the left temporal region, where the nail had penetrated the bone, a loose portion of the inner table about the size of a split pea came away. A corresponding perforation of the dura mater existed, but not a trace of inflammation could be found; no adhesions, increased vascularity, nor pus was present. Dr. Murray Lindsay is to be congratulated on having issued a very instructive report, giving unmistakeable evidence of the zeal and energy with which he conducts the important asylum confided to his care in all its departments.

SUPPORT OF LUNATIC ASYLUMS BY THE STATE.

THE following memorial has been forwarded by the Grand Jury of Londonderry to the Treasury :—

1. That the cure and maintenance of the insane poor in county asylums, with the new buildings and appliances required by modern medical science, form oppressive and increasing items in the county taxation and expenditure.

2. That if considerations of treatment, classification, and economy required the transfer of county gaols and prisoners to the care of the Imperial Government, the same reasons apply with greater force to the case of asylums and pauper lunatics, a vast proportion of the latter being totally incurable, and the remainder requiring special and immediate treatment, which often cannot be so well given in the same building.

3. That the principle of the liability of all property to the cost of the care of the insane poor is already established by the contributions now made of 4s. per head per week from the Consolidated Fund. The relief of local taxation by the removal of this burthen would be a just and sensible relief to the cesspayers, already highly taxed for public purposes.

4. That the payment of the cost of county asylums out of the surplus arising from the disendowment of the Irish Church would be of equal benefit to every part of Ireland, and in strict accordance with the spirit and intention of the Irish Church Act.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
„ IF PAID IN ADVANCE . . 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C
A. H. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—
MACLACHLAN and STEWART, South Bridge, Edinburgh.
A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

UBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, six dollars (£1 3s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistancies, Vacancies, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, SEPTEMBER 8, 1880.

VACCINATION METHOD.

THE Irish Local Government Board has just issued a circular of instructions to public vaccinators under its jurisdiction, which is valuable not only as a concise guide to what to do and what to avoid, but as a cautionary stimulus administered to the profession at the more appropriate moment. We can hardly venture to say—upon such positive information as is at our disposal—that the operation of vaccination is, in many instances, carelessly or inefficiently performed, but we do know that statements to that effect have been publicly made, and we are clear that it would be very unfortunate if any well-grounded suspicions should arise as to the efficacy of the vaccine operation. We rather think that, in some

instances, the "successful" case of vaccination for which the tax-payer pays the vaccinator's fee would hardly bear inspection, and we are under some apprehension that the "successful" cases so paid for frequently do not stand the test of small-pox infection. It is, indeed, hardly to be hoped for that an operation performed by dozens in the hurry of dispensary work would, in all cases, be very neatly and carefully done, although there may be every honest intention to make it effective. Moreover, the arrangements for a subsequent inspection of the vesicle are so cumbrous that it is not always that such inspection can take place at the right moment.

The Irish Local Government Board does not, however, either express or imply any doubt as to the working of the Irish vaccination system, nor does it put forth its suggestions in a mandatory form, and we hope that the recommendation which the department offers to its officers will be accepted with respect and cordiality, in which case we have no doubt that they will serve a good purpose and produce valuable results. We are unable to give the instructions *in extenso*, but we anticipate that our readers will be glad of the opportunity of learning the precautions which are officially approved by the Local Government Board, after, no doubt, the fullest consideration. We therefore give an abstract of the circular :—

INSTRUCTIONS FOR VACCINATORS.

Vaccinate only subjects who are in good health. Ascertain that there is not any febrile state, nor any irritation of the bowels, nor any unhealthy state of skin ; especially no chafing or eczema behind the ears, or in the groin, or elsewhere in folds of skin. Do not vaccinate in cases where there has been recent exposure to the infection of measles or scarlatina, nor where erysipelas is prevailing.

Lymph is to be used according to the following instructions :—

(1.) In proceeding to use a charged capillary tube—snip off its two ends ; then, from one end of the tube, blow the lymph through the opposite end upon the arm of one of the infants, over the place where the operation is to be performed, having had previously, two or three other infants' arms prepared for vaccination. The lancet is then to be loaded from the drop, and inserted into the arms of the children prepared to receive it, but enough is to be left upon the original arm to vaccinate that child. Unless the tube be very copiously charged not more than two children are to be vaccinated from it. The insertion should be made in four spots as hereinafter directed.

(2.) In operating with a charged ivory point *use no water to soften the lymph*. In this mode of vaccinating the operator should make a few scratches *just through* the cuticle, only sufficiently deep to *damp* the surface with *blood*. These scratches should *be made in four spots*, each covering a surface, at nearly one inch apart. The scratches may be abrasions of the cuticle by fine parallel lines, or by further cross-scratch. The operation may be performed on both arms when the surface available, or the position usually selected, is of limited extent. The operator should proceed with caution and take time. On no account should incisions be made and the point of the ivory inserted into them ; and it should be borne in mind that the vaccine virus ought not to reach the subcutaneous cellular tissue. The child should be kept under observation till the spots are perfectly dry, and orders given that the arms *must not be washed*.

(3.) Never either use or furnish lymph which has in it any, even the slightest, admixture of blood. In storing lymph, be careful to keep separate the charges obtained from different subjects, and to affix to each set of charges the name, or the number in your Register, of the subject from whom the lymph was derived.

(4.) Never take lymph from cases of re-vaccination. Take lymph only from subjects who are in good health, and, as far as you can ascertain, of healthy parentage ; preferring children whose families are known to you, and who have elder brothers or sisters of undoubted healthiness. Always carefully examine the subject as to any existing skin disease, and especially as to any signs of hereditary syphilis. Take lymph only from well-characterised, uninjured vesicles. Take it (as may be done in all regular cases on the day week after vaccination) at the stage when the vesicles are fully formed and plump, but when there is no perceptible commencement of areola. Open the vesicles with scrupulous care to avoid drawing blood. Take no lymph which, as it issues from the vesicle is not perfectly clear and transparent, or is at all thin and watery. Do not, under ordinary circumstances, take more lymph from a vesicle than will suffice for the immediate vaccination of five subjects, or for the charging of seven ivory points, or for the filling of three capillary tubes ; and from larger or smaller vesicles take only in like proportion to their size. Never squeeze or drain any vesicle. Be careful never to transfer blood from the subject you vaccinate to the subject from whom you take lymph.

(5.) Keep in good condition the lancets or other instruments which you use for vaccinating, and do not use them for other surgical operations. When you vaccinate, have water and a napkin at your side, with which invariably cleanse your instrument after one operation before proceeding to another.

This circular is, as we have said, particularly appropriate just now, and the Irish Local Government Board has done well to give utterance to some note of warning as to the future performance of vaccinations. The public mind should be, if possible, absolutely free of apprehension as to the efficiency of the operation, and we are convinced that the medical profession will willingly conform to any regulation which may be necessary to prevent any such apprehension arising.

"THE LADY DOCTOR."

THE good city of St. Mungo is extremely credulous. A few years ago it received the "Sulphur Cure" among all its ranks with absolute passion ; the "Vinegar Cure," begotten in Aberdeen, had to travel to Glasgow to obtain a receptive bosom ; and now it is a "Lady Doctor," which painful credulity has elevated on the pedestal of infatuated worship. It has been observed that not since the failure of the City of Glasgow Bank has this venerable city been so intoxicated. The antecedents of "the lady" are not of the most reassuring nature ; she is not likely to re-visit the scenes of former medical and surgical achievements. The method adopted of attracting the *ignobile vulgus* is the old charlatan one. The attire of the "wonder worker" is peculiar. She wears a coronet glistening with stones and metal that looks like gold, and a velvet bodice with spangles encircles her bust. She is said to be of Italian origin, and the daughter of a celebrated Roman physician, and to hold several diplomas. All this the people believe. Her carriage blazes with mirrors, gilding, and coloured glass, and so constructed as to afford room on its roof to about half-a-dozen musicians, likewise grotesquely dressed. Her horses are beautiful, and Madame handles them like a practised whip. She harangues the crowd through her interpreter, for she affects to speak no English. The lame, the blind, the deaf, the scrofulous, and all forms of suffering are presented to her for cure. She draws teeth dexterously with the old-fashioned "key," and the pain arising from broken jaws and stumps is deftly drowned by the musicians. She vends to a gaping and eager crowd two specifics, from the sale of which she must take about £300 per diem of the earnings of the credulous working classes. These medicaments are stated to be compounded

...ow *in the interior* of India and China, ... respectively the "China Caustic" and ... According to an analysis by Dr. Allen, ..., the "Chinese Caustic" of Madame Enault ...sed of wax, oil, vaseline, and some variety of ...tine!! And the "Indian Balm" consists essen... of glycerine and spirits of wine, scented with oil of peppermint and cassia!! That any charlatan is thus permitted to impose on the credulity of thousands with impunity simply amounts to a gross scandal. It is surely a matter with which it is competent for the Procurator Fiscal to deal. The law protects people from their own folly in many other directions. Psychologically, this craving after the miraculous seems deeply rooted in human nature; and it is astounding how people are imposed upon unwittingly by their own faculties, and how marvels grow as they are passed from mouth to mouth. From the medical point of view, it must be confessed that if there were such a thing as a *science* of medicine properly so-called, such melancholy exhibitions could never exist; the conviction is again forced upon one that the nearer the quack the greater the rewards, and that human nature in the nineteenth century is as receptive of the miraculous as it was in the first.

Notes on Current Topics.

Fasting or Starvation.

Mr. George Fleming, F.R.C.V.S., in the *Veterinary Journal* for September, referring to the supposed fasting experiment of Dr. Tanner, says that a similar cruel attempt was made with a number of horses in Paris in the spring of 1876. There was, indeed, this difference between the two cases—that the fast was forced upon the poor quadrupeds without their consent, and that there was a pretence of utility about the French experiment. The aim, as it was stated at the time, was to discover how long horses could go without food in the event of the scarcity which accompanies a state of siege. The following results were obtained from the inhuman experiment:—1. It was proved beyond all doubt that a horse can hold out for twenty-five days without any solid nourishment, provided it is supplied with sufficient and good drinking-water. 2. A horse can barely hold out five days without water. 3. If a horse is well fed for ten days, but insufficiently provided with water throughout the same period, it will not outlive the eleventh day. One horse, from which water had been entirely withheld for three days, drank on the fourth day sixty litres of water within three minutes. A horse which received no solid nourishment for twelve days, was nevertheless in a condition on the twelfth day of its fast to draw a load of 279 kilos.

The London Apothecaries' Hall.

Mr. Bradford, the representative of the "Hall" in the General Medical Council, sends to a medical contemporary an excerpt from the evidence which he intended to have given before the Select Committee of the House of Commons. Mr. Bradford, who has kindly furnished us with the following data, gives the average number of persons who, in three successive decades, have taken annually the licence of the Society:—

In the decade	1850-1859 . .	295·1
„	1860-1869 . .	291
„	1870-1879 . .	214·9

Thus it will be observed that a falling off of 26 per cent. in the licences granted within the past decade is confessed. But the decadence of the Hall did not really commence until within the last five years, and we suspect that a comparison of the licences granted in 1875-80 as against those granted in 1865-70 would show much more forcibly the real state of affairs

Food Supply.

There is an intimate relation existing between the health of a nation and its food supply, so that the greatest interest attaches to the arrangements by which the food material of the country is obtained. A very important source of the home-consumption, the American meat market, and those of other foreign countries, has associated with it risks that render it of the first importance to secure not only a regular supply, but one free also from disease, that the stock in this country may undergo no possibility of chance infection by beasts from abroad. The return of the Privy Council Orders having reference to the prevention of cattle disease has recently been issued, and from it we learn that between December 31st, 1878, and March 31st, 1880, £65,049 has been paid as compensation to owners for animals slaughtered by order of the local authority in Great Britain in 1879. In the same year a total of 1,239,696 animals were imported for consumption as food from foreign countries. The amounts named as paid for compensation seems a large one, but it is really only a small premium on the advantages conferred by the system of which compensation is a marked feature. The excessive care, too, shown in inspecting imported cattle is an admirable safeguard against the introduction of disease.

Hydrophobia in Scotland.

At the meeting in Edinburgh last week, of the Scottish Metropolitan Veterinary Medical Association, Professor Whally remarked on a number of cases of hydrophobia, which had either come under his immediate notice, or been reported to him by practitioners in and around Edinburgh during the present year. Careful examination of the details of all these, led him to the conclusion that it is not chiefly, as alleged, among the wandering homeless animals that the disease is principally manifested; but in almost every instance noticed, the animal giving rise to the madness was a "pet," or of some distinct breed. Retrievers and collies are named as the chief sufferers. Prof. Whally strongly urges Government interference as the only effectual means of dealing with hydrophobia. It must be "stamped out" by the introduction of rigid and complete measures of repression. Muzzling the animals is advocated with a wire instrument, and pitiless destruction of the ownerless and starving cats and dogs that infest the streets of so many town neighbourhoods.

Sir Edward Sinclair.

Dr. E. B. Sinclair, upon whom the Queen has conferred the honour of Knighthood, was formerly an assistant-surgeon in the 2nd Battalion 1st Royal Scots. He is a Fellow of King and Queen's College of Physicians, and King's Professor of Midwifery in the "School of Physic in Ireland," Trinity College, Dublin. In 1869, with the sanction and co-operation of H.R.H. the Field Marshal Commanding in Chief, the then head of the Army Medical Department, and the Board of Sir P. Dun's Hospital, he established "Sir Patrick Dun's Hospital School" for the education and training of women to serve as midwives in the army. Since its establishment the school has sent out 480 well-trained midwives and ladies' nurse-tenders for service in the army. The valuable services rendered by this nursing contingent have reflected honour on Dr. Sinclair, and has earned for him the approval of the army authorities, and we are gratified that Her Majesty has been advised to confer upon our *confrère* a distinction so well deserved.

Fasting as a Pecuniary Speculation.

The Barnum show initiated by Dr. Tanner is likely to have a good many imitators when it becomes known that to notoriety is added the "almighty dollar" sufficient to keep its wily performer in affluence for the remainder of his natural life. According to the calculations of the New York journals to hand, Dr. Tanner received altogether the sum of 137,640 dols. for his forty days' fast, or upwards of £27,530. This is at the rate of 3,441 dols., or £680 a day. This remuneration for forty days' gripes and grimaces is stated to have been made up from the following sources:—The doctor's own bets, 5,000 dols; through a betting agency, 12,223 dols.; sale of photographs, 1,500 dols.; payments for admission to the house, 78,915 dols.; from various manufacturers for the doctor's signature to their commodities, 11,102 dols.; gift from the University, 3,000 dols.; present from the state of Ohio, 5,000 dols.; and from the firm of Liebig and Co., 20,000 dols.

We hope the world is now satisfied with this gigantic swindle, and will hear with becoming equanimity of the doctor's quiet chuckles at his good fortune.

Sea Air.

The marked influence of sea-air as a restorative has been well shown in the case of Mr. Gladstone, who, after a short cruise in the steamer *Grantully Castle*, has returned to town in excellent health, and thoroughly restored from the illness which at one time assumed a threatening aspect. There are very many cases not entirely unlike that of the illustrious Premier which would benefit by a similar course of treatment; and though the efficacy of a short sea-voyage is often appreciated, it is yet too rarely resorted to by those who can easily avail themselves of it, and who, under gentle pressure from their medical attendant, would readily do so. This season, moreover, is peculiarly fitted for such excursions, and it cannot be too eagerly made use of by invalids, for whom the beneficial effects of pure sea-air are likely to have an important influence in determining the progress of their malady.

Hospital Sunday Movement Abroad.

The method adopted here of raising funds for hospital purposes by appealing to the general public in all places on a certain day has found favour in New South Wales; an attempt to fix a day for "Hospital Sunday" being vigorously made in Sydney. There has been some difficulty experienced from the fact that the principal medical charity, the Adelaide Hospital, is a Government institution, and being therefore objected to as a participator in the funds collected by a certain religious party. The aid of the Mayor of Sydney has, however, now been obtained in behalf of the attempt of the committee appointed to organise the movement, and there is every probability their efforts will be crowned with success.

Extraordinary Case of Ascaris Lumbricoides.

Dr. Fauconneau-Dufresne relates the following case in *L'Union Méd.*, May, 1880, which, as regards the number of worms discharged, he believes to be unique. In the year 1876, a lad, twelve years of age, exhibiting some symptoms of worms, some chopped garlic boiled in milk was administered to him, and in the course of the day he passed at different times fifty ascarides lumbricoides. He continued to pass more and more every day, so that he evacuated as many as six hundred in the same day, the worms being enveloped in a mucus resembling white of egg in appearance, and rolled up in a ball, separating themselves after their ejection. At first they were only passed by the anus, but in a short time they were expelled also by the mouth, and in the end exclusively by the latter. During five months he did not fail to discharge worms daily, generally from three hundred to four hundred. When Dr. Fauconneau-Dufresne first saw the boy, in July, 1878, he had passed fewer than for some time past, and he found him with a pale, puffed, and very emaciated face, eating much, but usually vomiting his food soon after he had taken it. Sometimes the worms were expelled with the food, but generally they were voided alone. The worms were discharged living, were five or six inches long, and about as broad as a quill. Besides the garlic, he had taken some pomegranate, and now castor oil and calomel, together with occasional doses of garlic, were prescribed. This treatment produced a continuous diarrhœa; but he had a good appetite, passed fewer worms, and was able to go out, and even to school. Seen again in January, 1879, when Corsican moss was prescribed. The worms were passed less frequently during this month, and in smaller numbers, and almost always dead. During February the moss was continued, with occasional purgatives, and the worms were much fewer, and dead. In March and April both dead and living worms were discharged; and at the end of the latter month santonine and calomel were prescribed. These had to be suspended from time to time, but the number of worms kept continually diminishing, and from August, 1879, to May, 1880, none whatever had appeared. The total number of worms counted during the three years, and for the most part ejected by vomiting, was 5,126; many more having also been passed without having been counted. The greatest number recorded by M. Duvaine amounted to 2,500, which were passed in the course of five months.

ompression of Aneurisms.

Bulletin de Thérapeutique, condemns the Bellingham and Broca, to the effect that total on gives rise to the formation of soft or passive an aneurism, while partial compression favours the ation of solid fibrinous clots, which alone conduce to pair. The author advocates the retention of digital compression during the first twenty-four or forty-eight hours, after which it should be intermitted at night to allow the patient to sleep. He considers that total digital compression offers advantages over any other means of treatment, inasmuch as (1) it is not dangerous; (2) it is more rapid in its action; (3) it is more often successful, and gives more brilliant results; (4) it has succeeded in cases in which partial compression has failed. He says that the reason why this treatment is most successful is because it most conduces to coagulation of the blood within the aneurismal sac.

Pauper Dress for Workhouse Patients.

Mr. Arthur Moore, M.P., has asked the Chief Secretary for Ireland—"Whether, in the case of persons not entitled to gratuitous relief, but seeking treatment for infectious diseases in Irish Poor-law hospitals, and willing to pay for the same, there is any regulation which precludes them from using their own clothing, and compels them to adopt the regular pauper-branded garments; and if such regulations exist, whether he is prepared to modify them, with the view of inducing the middle classes to avail themselves of these hospitals, and thereby raise the standard of medical treatment, and avoid grave dangers to public health." *Apropos* of this question, we may observe that there seems to be some danger that all the lower middle class patients suffering from infectious diseases throughout Ireland may be imposed upon the workhouse medical officers without any additional payment for attendance on such persons. The payment for which such patients are liable is simply the cost of their maintenance and medicine, without any sum for the services of the medical officer; and if Irish workhouses are to be made the refuge of the farmers and shopkeepers in all parts of Ireland, it is time that the Irish Medical Association took the matter in hand, with a view to the protection of the medical officers against imposition.

Replying to Mr. Moore, Mr. Forster said the regulations of the workhouse hospitals did not admit of patients wearing their own clothes; and that was a very necessary regulation, as otherwise, if convalescents returned home in the same garments as they had worn in a fever hospital, the disease would quickly spread. At the same time, there was no regulation that patients in a fever hospital should wear the regular pauper garments, and a circular had been issued to guardians forbidding it.

The Hospital Saturday Fund.

Last Saturday the annual collection took place in the streets of London in aid of the Fund, which was started some few years since, ostensibly with the object of enabling the working classes and others who did not frequent places of worship, to give something from their weekly wages on Saturday to the support of the hospitals which abound in their midst. For the first few years there was an evident want of confidence in the management of this Fund, and financially it was a failure. Recently it has got into better hands, and the contributions have proportionately increased. The present is the seventh anniversary, and some 400 ladies voluntarily gave their services, and took their stations in charge of the subscription boxes in various parts of the metropolis. In the vicinity of the public markets many took their places between five and six o'clock in the morning, and by half-past eight the most advantageous positions in the leading thoroughfares were occupied. A few minutes at any of these stalls quickly showed that the large proportion of money placed in the boxes was from those who would not legitimately come within the accepted category of the "working" class.

It is, of course, premature to hazard an opinion as to the result of this year's collection; we hope that, like the Hospital Sunday Fund, it will show a material increase.

Membership Fees at the London College of Surgeons.

The following special notice has been issued for the information of candidates for the Membership as to the payment of fees for the Primary and Pass Examinations:—

"All candidates presenting themselves for the first time, whether at the primary examination or at the pass examination for the diploma of member, will be subject to the payment of fees in accordance with the provisions of the following bye-law of the College, and all candidates who shall hereafter be rejected at either of these examinations will also be subject to the conditions of the said bye-law:—

9. "The fee of twenty guineas, over and besides the fee for the preliminary examination and the stamp duty, shall be paid by every person prior to his admission as a member. Every candidate for the diploma of member shall, prior to his first admission to the primary professional examination, pay a fee of five guineas, and such fee shall be allowed him as part of the said fee of twenty guineas payable on his admission as a member, and shall be retained whether he pass or fail to pass such examination. No candidate shall, after failure at any primary professional examination, be admitted to a subsequent primary professional examination without paying a further fee of three guineas, which shall be retained whether he pass or fail to pass such examination, but shall not be allowed as part of the said fee of twenty guineas. Every candidate shall, prior to his first and every subsequent admission to the final professional examination, pay a fee of fifteen guineas over and above all charges for stamps; but in every case of failure to pass such examination the sum of ten guineas and the charges for stamps shall be returned to the candidate. The fifteen guineas paid on admission to any final professional examination by a candidate who shall be successful thereat shall be allowed him as part of the said fee of twenty guineas payable on his admission as a member."

The *Broad Arrow* states that the Queen has caused a letter to be written to Mrs. Deeble, the lady-superintendent of nurses at Netley, thanking her and the staff under her orders for the excellent services rendered in Zululand. Though stricken down by fever in the middle of the campaign, Mrs. Deeble performed her duties to the last, and resumed them when she was barely convalescent. This is but one testimony from our troops in South Africa as to the efficiency of our nursing establishment.

Bequest to the London Hospital.

THE London Hospital has received a sum of £1,000 from the rector and churchwardens of the parish of St. Edmund the King and Martyr, City, who act as trustees of a fund arising out of a charity belonging to the parish. This timely bequest will probably serve to improve the financial condition of the London Hospital sufficiently to enable a further postponement of the unfortunate time when it shall be found necessary, through inadequate support, to close any portion of what is the most important public charity in the metropolis.

Infant Mortality in the Belfast Workhouse.

IN reply to a question put by Mr. Arthur Moore, M.P., whether his attention has been called to the statement in Dr. M'Cabe's recent report on Belfast workhouse, that within the six months from January to June eighty-two infants have died in that institution; and if he would inform the House what percentage of the whole number of infants this represents, the Chief Secretary replied that the ratio of mortality was 30 per cent. This is nearly as bad as the "Butcher's Bill" of the old Foundling Hospital in Dublin, in which institution, under the management of pious ladies, Archbishops, Lords, and people of fashion, 92 per cent. of all the infants were annually made away with for a long series of years. Subsequently Mr. Moore gave notice that next session he would move a resolution demanding a reform of the Irish Poor-law and its administration.

Xylotherapy.

AT a recent meeting of the Société de Therapeutique, M. Dujardin-Beaumetz read for M. Jourdanis a note on the Æsthesiogenic properties of certain woods applied to the skin: which he calls xylotherapy (*La France Medicale*). M. Jourdanis has applied plates of wood to the insensible skin, and as with plates of metal, magnets, sinapisms and blisters, has obtained a return of sensibility. The applications of wood seem to be more active than the other means. All woods do not act with equal intensity, and with regard to their efficacy may be classified in the following order:—Cinchona bark, thuja, rosewood, mahogany, pitch pine, walnut, maple, apple; poplar, ash, and plane produce no effect. Return of sensibility is accompanied by congestion of the skin. We cannot suppose these phenomena to be caused by electric currents.

The Small-pox Epidemic in Dublin.

THE week ending the 28th ult. was the first since that ended Saturday, 2nd February, 1878, in which there was not a death from small-pox registered in the Dublin Registration District. Seven new cases of the disease were admitted into the Dublin hospitals during that week, being 2 over the admissions in the previous week; 16 patients were discharged; and 39 remained under treatment on Saturday last, being 9 under the number in hospital on Saturday, 21st inst.

Deaths from diarrhœa, which in the two preceding weeks amounted to 23 and 25 respectively, rose last week to 36. Thirty-one of these deaths were amongst children under 5 years of age.

Epilepsy from a Foreign Body in the Ear.

DR. KATZ, of Berlin (*La Presse Medicale Belge*) had recently under his care a woman, æt. 30, who had never shown the least sign of hysteria or any other disease of a nervous origin. For a year she had had very troublesome noises in the ear, and about the same time became subject to epileptiform attacks, at intervals of one or two months. All the means employed to cut short these attacks were fruitless. When Dr. Katz saw the patient, at the end of last year, he was not long in discovering at the bottom of the left auditory meatus a black mass which was extracted with some difficulty, and was found to consist of a roll of cotton wool covered with cerumen. Freed from this foreign body, the woman found herself relieved at the same time of the disagreeable sensations in the left ear, and the convulsive fits.

The Responsibility for Irish Non-Sanitation.

THE *Ballina Herald*, in quoting our recent observations in reference to the responsibility of the Irish Local Government Board for the disgraceful state of sanitary affairs disclosed by Dr. Nixon in his "Famine Fever Report," says:—

"We can affirm ourselves, if need be, the truth of the statement, that the salaries given the sanitary officers are nominal; and boards of guardians, as a rule, are not much concerned as to the way in which the duties are discharged. There must be great negligence when the medical commission lately round were able to see so much that was bad, and had to write in such strong terms of condemnation."

Treatment of Pseudo-Membranous Colitis by Euonymin.

DR. BLONDEAU brought before the Société de Therapeutique recently (*La France Medicale*) a case in which he had employed euonymin in one of his patients suffering from pseudo-membranous colitis which had been vainly treated by the most energetic remedies. He prescribed—Euonymin, 0·05 grammes; extract of hyoscyamus (B.P.), 0·10 grammes—made into two pills, one to be taken morning and evening. After six days of this treatment, the patient had regular motions, and recovered her health, which she had lost for some months.

Treatment of Herpes.

M. A. FOURNIER (*La France Medicale*) recommends, after washing the ulcerated vesicles of herpes with hypochlorite of soda solution diluted with half its volume of water, that the wound be covered with cotton wool impregnated with the following powder — subnitrate of bismuth, 4 parts; calomel and oxide of zinc, of each, 1 part. If the eruption is extensive, he recommends absolute rest, the administration of baths with bran or starch, and the internal prescription of opium and bromide of potassium.

Two very eminent members of the profession on the Continent have passed away during the last few days, in the persons of Professor Hebra of Vienna, and Professor Paul Broca of Paris; both were brilliant lights in the world of medicine and science.

The Constabulary and Dr. Stevens's Hospital (Dublin.)

On the motion of Mr. Callan, M.P., a return has been ordered of all correspondence between the Inspector-General of Constabulary and the Governors of Dr. Stevens's Hospital relative to the treatment of constabulary patients in the said hospital, referred to in a letter of T. H. Burke, Esq., Under Secretary, to the Secretary of the Board of Superintendence of the Dublin Hospital, under date the 24th day of October, 1878.

Dr. Andrew Scott Myrtle, of Harrogate, has been appointed a Justice of the Peace for the West Riding of Yorkshire.

A distinguished service reward of £100 per annum has been conferred upon Sir W. M. Muir, M.D., K.C.B., Director-General of the Army Medical Department.

Dr. Bateman of Norwich and Dr. Hack Tuke of London have been elected Corresponding Members of the Society of Psychiatry of St. Petersburg.

Our American exchanges report that Dr. Tanner intends lecturing on the "Secret of Fasting," so soon as he shall have sufficiently recovered strength.

The wife of a labouring man, in the Old Kent Road, was last week delivered of four children at a birth, three boys and a girl; two only have survived. The mother on a previous occasion had given birth to twins.

Last week a surgeon was committed for trial, in a case brought by the United Kingdom Assurance Corporation, charging him with receiving 7s. 6d., with fraudulent intent, for certifying to the eligibility of certain lives, without previous personal examination.

The New York papers state that the notorious medical diploma monger Dr. John Buchanan, of Philadelphia, who was under bail for fraud, has ended his career by suicide. Incapables will again have to turn their eyes to Germany where there are yet one or two institutions open to a quiet bid.

To hydrophobia was assigned the death of a little girl last week, in Belfast. Deceased was bitten by a rabid dog on the 21st of July last, and was conveyed to the Belfast Royal Hospital, where the wound was cauterised. Three days before death symptoms of the disease manifested themselves, and nothing could avert the fatal termination.

The annual rates of mortality per 1,000 last week in the large towns of the United Kingdom were—Bristol 16, Edinburgh 17, Glasgow 19, Oldham 19, Plymouth 21, Portsmouth 21, London 21, Brighton 21, Bradford 24, Newcastle-upon-Tyne 26, Birmingham 27, Wolverhampton 27, Sheffield 30, Leeds 30, Sunderland 31, Hull 31, Norwich 32, Nottingham 32, Manchester 33, Salford 33, Leicester 35, Liverpool 35, and Dublin 38.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 22, Bombay 24, Madras 35; Paris 27; Geneva 26; Brussels 32; Amsterdam 28, Rotterdam 21, The Hague 21; Copenhagen 29; Stockholm 32; Christiania 30; St. Petersburgh 37; Berlin 34, Hamburg 28, Dresden 26, Breslau 36, Munich 27; Vienna 23, Buda-Pesth 41; Turin, 26; Venice, 23; Alexandria 38; New York 27, Brooklyn 27, Philadelphia 17, and Baltimore 20 per 1,000 of the population.

The death rate from the seven principal zymotic diseases in the large towns last week ranged from 4·6 and 4·9 in Bristol and Brighton, to 15·7 and 20·9 in Salford and Leicester. Scarlet fever showed the largest proportional fatality in Norwich, Sunderland, Oldham, and Salford; and fever in Salford, Leeds, and Sheffield. Small-pox caused 3 more deaths in London, but not one in any of the other large towns. The deaths referred to diarrhœa, which had steadily increased in the ten preceding weeks from 51 to 864, further rose last week to 994, and were equal to an annual rate of 6·9 per 1,000. The death rate from diarrhœa was equal to 3·8 in London, and to 9·7 in the twenty large towns, among which it ranged from 2·7 and 3·2 in Oldham and Bristol, to 13·0 and 18·1 in Sheffield and Leicester.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

The Medical Officer of the Edinburgh City Poorhouse.—A special meeting of the Edinburgh Parochial Board was held on the 31st ult. in the Board-room, Forrest Road, Mr. David Kinnear, chairman, presiding, to "consider recommendation by the house committee that the services of Mr. Furley, the Medical officer to the poorhouse, be dispensed with." The inspector, Mr. Greig, read the minute of a meeting of the house committee, held on the 18th August, which stated that the chairman had reported that Mr. Furley's conduct of late had been far from satisfactory; that he had desired the inspector to write to him requesting him to attend an interview, and that the letter had been returned through the Dead Letter Office, marked "Left; no address." The committee having considered the matter, appointed a small sub-committee to meet with Mr. Furley, with the object of endeavouring to procure his resignation. At a subsequent meeting of the committee on the 27th August the sub-committee reported that they had failed to obtain an interview with Mr. Furley, and therefore recommended that his services should be dispensed with. The chairman said that unless any gentleman had any remark to make, the less they said regarding the matter the better; and he was prepared to move that the recommendation of the house committee be adopted, and Mr. Furley be dismissed from the service of the Board; and that the inspector be instructed to intimate this to him formally. The motion was unanimously agreed to without further remark. Mr. Furley's assistant was appointed medical officer to the house *ad interim*, and a committee was appointed to consider what steps should be taken to fill the vacancy, and to report to the next meeting of the Board.

"The Queen of Scotch Watering Places."—The authorities of Oban contemplate applying to Parliament for a Bill to

enable them to furnish the burgh with an adequate supply of fresh water. As there are few towns in the kingdom which, for beauty of situation and salubrity of climate, can compare with this rapidly-rising and fashionable watering place, the expediency of the proposed scheme is apparent. Oban possesses every attraction to the pleasure or health seeker, and those who are entrusted with the management of municipal affairs should do all that lies in their power to make the place attractive. In addition to obtaining an adequate supply of good water, offensive smells, of which there are at times really too many here, should be kept down, and facilities should be afforded to bathers which do not at present exist. With due circumspection in a sanitary direction there is no reason why this fair town should not take foremost rank as a health as well as a pleasure resort; and all personal differences should be subdued in presence of the good and pleasure of the public, both local and strangers.

The late Dr. Alexander Forbes.—Dr. Alexander Forbes expired in his house, North Silver Street, Aberdeen, on the 29th ult. The deceased was a native of Aberdeen, and after attending the Arts Classes at King's College, entered the Medical School at Marischal College. He subsequently completed his professional training in the Universities of Edinburgh and Paris, and commenced to practice in Peterhead in 1867. He remained there about three years, and at the end of that period removed to Aberdeen, where he assumed the practice of Dr. Coutts, Golden Square. Dr. Forbes was physician to the Epidemic Hospital, Blair's College, Nazareth House, and the Orphanage, Constitution Street. He was much liked by his patients for his quiet, gentlemanly bearing, and unfailing kindness; and by these, as well as by a large circle of friends, his untimely death will be greatly lamented. For a considerable time Dr. Forbes had been suffering from a lung affection, and to that he succumbed. He was 38 years of age, and leaves a widow and four children.

The late Dr. Hirschfeld, of Banff.—Dr. Hirschfeld, of Banff, with his only son, aged 4 years, were accidentally drowned on the 31st ult. The deceased gentleman was highly respected in Banff, and had only attained the age of 33 years. He was Visiting-Surgeon to Chalmer's Hospital; Visiting-Physician to the Banffshire District Lunatic Asylum; and served with distinction in the British Ambulance in the Franco-Prussian War.

Registrar-General's Returns.—According to the weekly return of births, deaths, and marriages for the eight principal towns of Scotland the death-rate for the week ending with Saturday, the 28th August, 1880, was 18·4 per 1,000 of the estimated population. This rate is 1·3 above that for the corresponding week of last year; and 0·2 above that for the previous week of the present year. The lowest mortality was recorded in Greenock—viz., 13·1 per 1,000; and the highest in Leith—viz., 28·4 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 5·0 per 1,000—nearly the same as for the previous week. Acute diseases of the chest caused 55 deaths, being 16 more than the number for last week.

Correspondence.

A SIMPLE CURE FOR ASTHMA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I beg to call your attention and that of your readers to an extraordinary cure of a case of asthma, following severe bronchitis, of eight years' standing. I should have long hesitated to do this had I not been treated by, and well known to, so many eminent members of the profession. My long and severe suffering I cannot describe, nor would it serve any good purpose were I able to do so. Very many of my friends, as well as my own family, were witness to them, but the sufferers from asthma alone can understand them. I tried the various specifics, but the only relief I got was from change of climate, wintering in Tangiers, Spain, at sea, or in the south of France, but soon after my return the old enemy attacked me and rendered me unable to take any pleasure or do any work. During the night I was always awakened by a feeling of suffocation, which obliged me to sit up and pant for breath sometimes for an hour, but more frequently for two or three hours. Of course, I tried every remedy kindly prescribed for me; I dieted myself as recommended. I was very careful in going up stairs, frequently going up backwards; and taking care to lie down very gently. By observing these rules the difficult breathing caused by the exertion of going up stairs and undressing became easy, and I got to sleep, which usually lasted until the suffocating feeling above described came on. You will readily imagine that I did not get fat, and it was far from pleasant to be accosted several times a day by friends with the remark, "How thin you get." I am now well, and can walk and run without difficulty. This to me seems like the transformation scene in a theatre, so sudden, so striking, so delightful; and I should be not only intensely selfish but extremely wicked did I not tell you, and through you the public, how this relief has been obtained by me, and how all others similarly afflicted may obtain it. I was telling a valued and intelligent patient my griefs, and after listening to them she said, "I feel sure that Ling's movement cure would relieve you, if it did no more." Sinking men, it is proverbial, catch at straws. I readily caught at what I then thought a straw. Hear the result: I have only been under treatment a week, one hour daily, and I can say most truthfully that I am well; and am thankful to my patient who first mentioned the treatment to me; and most grateful to Major Leffler, 11 York Place, Baker Street, to whose skill and unremitting care I owe the good health I now enjoy. I have no difficulty in going upstairs or exerting myself in any manner, and, what is more delightful, I am free from night attacks. I have already gained three pounds in weight, and the Major thinks that I may regain my usual height. This, to a man who has seen seventy-seven summers, seems fabulous; but from what has already been achieved, I firmly believe it. I am, Sir,

Your obedient servant,

George Dunn, M.D.

42 Gordon Square, London.

Literature.

INDIAN NOTES. (a)

A chatty and pleasantly written book is that which bears the above title; replete with information is it also, although truth to tell, there is, in some of its pages, a *leetle* laxity of expression, such as might have been avoided had the author been less hurried than he appears to have been when running off his *copy*. His work begins with his voyage to India; then come in succession chapters on Travelling in India, in Upper India, Stations, the Hills, Mineral Waters, and lastly, Herbs and Simples. All these, with perhaps the exception of the two last, being interesting to the general reader, as well as to the medical. The author in compiling his *Notes* has, evidently, done a great deal of reading; and, as among the subjects touched upon by him, are two which are, at present, being very much discussed, not only in India but in England, namely, cholera, and *typhoid* or *enteric fever*, we propose to follow him somewhat at length in his remarks on these diseases.

1*st. Cholera.*—The circumstance is noticed that at Allahabad this disease has not appeared during the eight previous years among the prisoners, although other classes in the station have suffered from it; the first appearance taking place in March, reaching its climax in May, decreasing till July, re-appearing in August, and continuing till October. Marching into camp four miles off did not answer, so the troops were

(a) "Indian Notes." By F. R. Hogg, M.D., Surgeon-Major. J. and A. Churchill. London. 1880.

sent by rail thirty, then forty, miles down the Jubbulpore line, and thus the plague was stayed. At Cawnpore much the same rate holds good in regard to seasons of prevalence; there it was found expedient to march out eleven miles, rather than encamp at short distances from the station. At Delhi, in 1875, during a cholera period, nine inches of rain fell in one September day, without, in any degree, interfering with the course of the disease. In the same epidemic five hundred cats infected with round or tape-worm, died in that city. At Forozepore, in 1867, heat-apoplexy was followed by cholera, traceable to importation, and in no way associated with diarrhœa in its early stages; it attacked fatally a few healthy temperate men. At Fyzabad the disease appeared as an epidemic in the month of April in each of the years 1860, 1864, and 1870. At Jullundhur mild outbreaks took place in 1857, 1858, 1867, 1868, and 1872. At Kohat outbreaks were specially noted in 1858, 1862, 1867, 1869, and 1872, generally commencing in August, and ending in October. At Lahore the disease usually prevails during these two months. At Lucknow it, as a rule, commences in the European infantry lines, and though attributed to pilgrims and punkah coolies, "appears to depend more on season than contagion." At Meerut, in 1867, the British troops at Meerut suffered severely, while the native troops and the jail prisoners escaped. The disease was, on that occasion, evidently imported by pilgrims from Hurdwar; after the disease had appeared, "every variety of sanitary measures in camp or barrack failed to diminish the mortality, or mitigate the malignant virulence" of the pestilence; cholera and malarial fever became associated in the same barracks. At Kirkee, in April, 1867, after a continuance of dry hot weather, a thunderstorm occurred; down came pouring rain upon a band of pilgrims, out came the sun; next morning they drank foul water, and became immediately attacked with cholera, which they spread in all directions. At Umritzur cholera is often accompanied by malarial fevers. At Umballah these two diseases ran concurrently together; but "since the dykes prevented country inundation, cholera outbreaks, severe in 1845, 1852, 1857, 1861, and and 1867, do not figure largely in returns."

2*nd. Typhoid or Enteric Fever.*—Dr. Hogg says "the newly arrived young soldier in the plains, and not unfrequently at crowded insanitary hill stations, may too often be attacked with enteric, especially if exposed to the blazing morning sun, to extreme fatigue, to bad food, overcrowding, or if stationed in a place annually becoming more polluted after prolonged occupation." At Bareilly it attacked young, unseasoned, susceptible new arrivals from England. At Delhi, "according to ancient annals," fevers are prone to cerebral and typhoid complications. At Fyzabad in 1878, it "fastened" on those susceptible, and preceded by febricula or tonsillitis, proved to increase in intensity from April to June, *i.e.*, during the season of dry heat. At Hazarabagh "formerly aloe hedges obstructed ventilation, and rice fields near the barracks favoured fevers, and yet regiment after regiment liked the place until enteric fever, fastening on those susceptible, necessitated the reduction of the troops to a detachment. A number of sanitary improvements followed, and since 1874, scarcely any enteric returning, it was considered safe to locate more men. At Jullundhur in 1868, from May to August, and onwards, *i.e.*, the rainy season, the 92nd regiment suffered from enteric fever originating within the regiment itself, and supervening on an outbreak of diarrhœa, which commenced on the voyage up the Indus among the young children, extended to the larger children and women, and lastly to the men, especially to young weakly recruits. No special prevalence of enteric at the same time affected seasoned recruits. In 1878 the 100th regiment at the same station, having only arrived from England in the previous December, suffered from typho-malarial fever, which, proving terribly fatal to many men, women, and children, yet spared the officers. But for periodic outbreaks of flood fevers, Jullundhur would be one of the most coveted stations. Kurnaul was an important place until pestilential fever compelled the troops to leave it for Umballah in 1843. At Loodianah, in 1857, the whole district was temporarily a marsh; a prostrating fever fastened on Europeans and natives with equal intensity. At Lahore, in 1849, "enteric fever, with cerebral complications, originated in the small barracks crowded with European Bengal Fusiliers. In June the fever became more distinctly typhoid when not replaced by gangrenous dysentery. In July it fatally selected unseasoned recruits, and cases of heat-apoplexy became frequent at a time when the river Ravee was inundating the country. In September fever and dysentery increased as the ground dried up, and in October matters became worse and worse as scorbutic dysentery became developed. At Rawul Pindee, "during hot dry months, typhus may be endemic in the district and in the jail; either contagious typhus, relapsing or enteric fever, if not typhoid pneumonia," has occasioned controversy. Remittent and continued fevers prevail in August, intermittent in October. At Umritzur the fever type is pitiably exhausting, somewhat akin to that of Ferozepore and Meean-Meer. Subathoo has, for a long time, been named as the home of a typhoid form of malarious fever.

A good many valuable remarks of miscellaneous nature occur in Dr. Hogg's book. He says, with truth, that in India, "an amazing amount of liver disease can be traced to the indulgence of a *craving* for beer." This is quite correct, and, indeed, there are not a few medical men who look upon the habit of beer drinking among our countrymen there as even more pernicious to health than the habit of spirit drinking. He casually mentions the circumstance that "opium in fever-stricken villages is food and medicine;" but, unfortunately, gives no further information upon this important subject for inquiry. At Meerut, during sickly months, cattle suffered from lassitude, diarrhœa, aphthæ of the mouth, œdematous throat and exhaustion; "*red* thread worms, half an inch long, were found in the large intestines and stomach, yet not in the excreta."

ON THE BILE, JAUNDICE, AND BILIOUS DISEASES. (*a*)

THIS is a captivating-looking book: is a large handsome octavo that reflects every credit on the publisher. It further demonstrates its author's intimate acquaintance with the literature of the subject, from the observations of Hippocrates to the experiments of Rutherford. But, nevertheless, it is an utterly exasperating book. The information we desired, and which the author doubtless could furnish, we cannot find; it eludes one's search like a Will-o'-the-Wisp. Chapter after chapter marches before us in stately procession, replete with quotations and research, reminding us forcibly of Gibbon's renowned History. There is, too, the same mocking, sneering spirit running through the tome from beginning to end. In order to demonstrate that this is not either captious criticism or personal hostility to the author, we will let him speak for himself. He concludes his chapter "On the Bile" so:—"It thus becomes possible that the bile-pigments, after suffering whatever chemical change they may be destined to undergo in the bowel, are absorbed into the blood and so excreted by the urine as colouring matter, while the remainder passes out with the fæces. The end of the bile would thus seem to be excretion by the urine—a view not altogether new, for it was taught by physiologists 1,600 years ago that the urine was formed in the liver and separated by the kidneys; and those who come after us may judge whether the nineteenth century have made any real progress in this matter compared with the age of Galen." Then, again, he concludes what he has to say on "The Treatment of Jaundice" with —"With Bamberger we may regret that not a step has been made forward in the treatment of jaundice for 2,000 years, and that the therapeutics of this age are, in all essential points, the same as those of Hippocrates and the early Greeks."

The final chapter is "On Bilious Diseases," and concludes as follows:—"The humoral pathology will, however, not be readily overcome. It has survived many an onslaught during the last 300 years, even when attacked by a Paracelsus. And if we find the writer of a justly popular handbook of physic (Niemeyer) still speaking of 'mucous fevers,' and the public still saturated with the humoral physiology as the terms 'sanguine,' 'phlegmatic,' and 'melancholic' show; as does also their familiar parlance on medical matters, 'the blood being out of order' (a main source of disorders), 'venting of spleen,' and the like expressions; he would be a bold man who should foretel the driving of this system of pathology out of its citadel. 'Bilious complaints' with the public will therefore in all likelihood hold their own. In the now fashionable jargon 'bilious chill'

(*a*) "On the Bile, Jaundice, and Bilious Diseases." By J. Wickham Legg, Assistant Physician to St. Bartholomew's Hospital, and Lecturer on Pathological Anatomy in the Medical School. H. K. Lewis. 1880. Pp. 664.

is talked of, though what is meant appears equally a mystery either to the scientific or non-scientific mind."

The work is a perfect storehouse of matter for those who wish to "drink deep at the Pierian spring;" but for the general bulk of the profession it is scarcely adapted. The late Dr. Murchison taught us something practically valuable from recent research, in his "Functional Disorders of the Liver" especially, for which the whole profession is grateful. Dr. Legg marshals his facts and material to teach nothing but scepticism. With his information on the subject with which he deals, he has a magnificent opportunity of gaining the ear of the profession and the public. He seems, however, to have revelled in the idea of perversely wasting the opportunity, and flinging it away in sheer impish sportiveness, in absolute derision. Instead of the voice of the teacher there is a mocking sneer, and we very much regret that we feel compelled, much against our will, to say so.

CLIMATE AND MEDICAL TOPOGRAPHY IN THEIR RELATION TO DISEASE. (a)

THE work now before us furnishes one more example of the valuable labours performed by that once glorious Service, the Indian Medical. Indeed, it was only while writing his *preface* that the author became aware of the vast change that had just passed over the body of which he is one of a very long list of ornaments; he accordingly in a foot-note enumerates *some* of the many benefits that his Service has conferred on India, and then adds this sentence, in the truth of which all who are acquainted with that great Empire cannot but most fully agree: "The history of the Indian Medical Service, now alas, it is to feared about to lose its independent existence, would form a history of beneficent British work in India of a kind which the people of the whole land would thoroughly understand and gratefully approve." A noble Service indeed it *was*.

The work before us opens with a general description of the mountains and plains of Northern India, including their geology and river systems. Next follows an elaborate series of tables containing the results of analyses of waters made with a view of determining the amount of lime and magnesia contained in those of goïtrous districts, the result being to disprove the view that an excessive quantity of those salts in drinking water is an efficient cause of the disease. He is of opinion that "the disease depends on some influence which can develope itself very locally independently of any local differences which we can at present recognise in soil, water, or climate." The subjects of *malaria* and of *fever* in relation to rainfall are discussed at length. With regard to the former he asks: Does malaria simply express the result of certain climatic influences? and to this query he for himself answers in the affirmative, as no doubt the majority of his readers will be disposed to do also. It is true that he subsequently discusses the *specific poison* theory of malaria, but apparently with no very definite result, notwithstanding that, as he observes, "we have the history of epidemics of fever of a distinctly malarious character which from time to time invade parts of India which cannot be accounted for by changes meteorological or telluric, by contagion or infection, and can only be attributed to the widespread development of some specific poison." Why *specific* poison? Is not this theory of specific *poisons* somewhat too freely applied at present? Might we not with equal, if not a good deal more, propriety substitute for it the word *influence*?

A very valuable and detailed account of an epidemic of malarial fever which prevailed over a great portion of upper India from August till October 1869, "affecting native troops and the civil population alike, and apparently in its character resembling the disease by which, in 1809, our troops in Walcheren were devastated." Three forms of this fever were recorded in India: thus at Jullundhur there was the ordinary quotidian intermittent; 2, that which, beginning as a quotidian, then became a tertian in the latter stages, attended by diarrhœa, anæmia, and anasarca; and 3, beginning as an intermittent, then suddenly taking on a low *typhoid* type, generally being fatal, from seven to eleven days. This last form is of especial interest in reference to the discussion now taking place as to the existence among British troops in India of *specific* enteric fever, as against endemic fever with typhoid state or intestinal complications. Another important remark occurs with more particular reference to a somewhat similar outbreak of fever which affected the Naval Brigade and 6th Foot at Buxar, in the latter end of 1859, namely, that "an epidemic malarious fever may manifest itself in the mildest form of intermittent, or, according to circumstances, prove so malignant that in a few days the patient sinks into the *typhoid* condition of the worst description of jungle fever." Prisoners appear to enjoy a remarkable degree of immunity from epidemics of malarial disease, a circumstance accounted for by the fact of the prisoners being shut up at shortly after sunset, and sleeping in dry and well-raised wards.

Unfortunately the space at our disposal does not permit us to enter more at length into the analysis of this valuable and comprehensive work; we may hereafter make use of the ample store of information contained in it, and in the mean-time can only recommend it most highly to all who are interested in the medical history of India.

(a) "Climate and Medical Topography in their Relation to the Disease-Distribution of the Himalayan and Sub-Himalayan Districts of British India, &c., &c." By F. N. Macnamara, M.D., F.R.G.S. London: Longmans, Green, and Co.

MEMOIRES DE CHIRURGIE. (a)

THIS is a most important contribution to the histology and pathology of clinical surgery. M. Nepveu, who has been long known as the very distinguished conductor of the laboratory of the Hôpital de la Pitié, of Paris, has assembled in one volume the results of numerous observations made by him in the clinical wards of that hospital, and especially in those of the greatly respected teacher, M. Verneuil, the pride of Parisian surgery.

In M. Nepveu's work we find first of all a most exhaustive essay of 160 pages on the most important question of bacteriæ and their influence in disease. Following this is a short paper on the extirpation of melanic tumours. Then a paper on lymphangioma, followed by one on denudation of the nerves. Next follows a contribution on certain ulcers of the integuments seen in atrophic paralysis of infants. Then a paper on ostioclasis and osteotomy, one on adenochondroma of the sub-maxillary gland; then one on the accidents arising after ligature of the common carotid artery, one on traumatic oliguria and anuria, and one on oliguria and polyuria caused by reflex action originating in the testes. There is a long and most important essay of no less than 70 pages, on tumours of the testicle, an obscure subject, on which M. Nepveu here throws a flood of light. Another chapter is devoted to rupture of ovarian cysts, followed by one on melanic tumour of the rectum and anus. There is next a valuable paper on some vascular lesions occurring in fractures of the leg; and finally, a paper on the atrophy of the fibro-fatty mass under the metatarso-phalangeal articulations.

Readers of practical surgery must be difficult to please if they do not find in some of these elaborate essays a chapter to their taste. Space fails us to do justice to the work, but we will mention one or two of the most salient points. "The success," says our author, "of the antiseptic method may be attributed as well to a chemical theory as to that of a germ theory. This doubt, which is purely a scientific one, ought not to be any cause of failure of purpose for the practitioner. The simple antiseptic method in its essence, varied according to Lister, Guerin, &c., is followed by constant successes by all who make themselves its interpreters in an intelligent manner in the practice of surgery. In the medical point of view, we may also, whilst only giving to the bacteria the place of indifferent corpuscles perhaps, yet establish their importance in the same way. Thus, certain authors explain how that in certain epidemics of various nature, these agents are, according to the primitive focus whence they emanate, the most facile spreaders of the most terrible epidemics."—P. 137.

Speaking of melanotic tumours our author observes, page 159, "In short, melanotic matter is a derivative from the blood. This is proved by the existence of a colour varying from yellow to reddish-brown, or to black in the melanotic tumours, as well as by the presence of yellow matter and

(a) "Memoires de Chirurgie." Par le Docteur Nepveu, Chef du Laboratoire de la Clinique Chirurgicale de la Pitié. Pp. 720; with Two Plates. Paris: Delahaye. 1880.

blackish granulations in the cells (cellules of the tumour, or plastic cells), and even in the capillaries, the glands, and cutaneous epithelium which are perfectly healthy, besides which we find local alterations of the blood in the tumour itself."

Diffusion and hæmorrhage are the two causes of the exudation of the colouring matter from the vessels. It is probable that the elaboration which is the property of the cells themselves has something to do with the intensity of the colouration and the rapid metamorphosis of the colouring matters. Melanosis is then only an accident in certain tumours, and we may thus comprehend why certain tumours are partially melanic.

In his essay on atrophic palsy of infants Dr. Nepveu shows that vesicular eruptions, ulcerations, and even arthritis may arise, all which are quite analagous to those which have been described by writers on the diseases of the nerves, in certain lesions of the nerves, and of the cerebro-spinal axis. These alterations are essentially trophic in character, as shown by the lowering of the temperature, &c. The ulcers have not been hitherto well described by physicians. These may last a long time, and their cure may be hastened by electricity.

In a short paper on oliguria and anuria caused by traumatism, Dr. Nepveu mentions that the testes may, in certain abnormal conditions (injection of iodine into the t. vaginalis, acute inflammation, &c.), be the origin of reflex actions which act on the urinary secretions. This reflex action, especially in the case of hydrocele, treated with iodine injections, is shown by a series of oscillations in the secretion. Oliguria takes place for a few days, then polyuria.

A series of articles on diseases of the testis follow. Our author speaks first of the pearly tumour of the testis, and observes that this takes its origin from the epithelium of the organ; the cysts which accompany it arise from the canaliculæ of the testis. Epithelioma, adenoma, and atheroma of the testis arise in the same way. Encephaloid of the testis is often a mixed tumour consisting of different epitheliums of the seminal parenchyma; of vascular epithelium, lymphatic epithelium, and testicular epithelium. All these are affected simultaneously with the conjunctive tissue. Some of these correspond to the lymphoid sarcoma or lymphadenoma of certain authors. Schirrhus of the testis, a rare form of cancer of the organ, is found in rather advanced life, and is not amenable to treatment. Tubercle of the testis exists under the three forms: grey granulation, fibrous tubercle, and disseminated tuberculosis. The two former forms may be isolated, or united in masses. Benignant fungus of the testis is rather common in Italy, but rare in France. It is seen under three forms: the inflammatory, tuberculous, and syphilitic, the two latter being the most frequent. Anatomically this affection has two forms which are essentially different. The one consists in the formation of fungus granulations (1) on the tunica albuginea, and (2) on the testis. In these two cases the testis remains healthy. In the other form there is a loss of substance in the tunica albuginea, through which the testis is apt to protrude. In the case of gummata of the testis we have, firstly, the characteristic aspect of the testis on a fresh section being made of it; secondly, the tertiary or other syphilitic symptoms; thirdly, the existence of interstitial orchitis in a cheesy state. In case of hæmorrhagic vaginalitis, Dr. Nepveu found the vessels of the testis increased in volume, the walls much thickened, but infiltrated with cells of the same kind. This process is, he says, entirely different from what is seen in tuberculosis, and appears to be due to a vaginalitis or epididymitis with effusion of blood.

Melanic tumours of the rectum, says our author, which are rather frequent in the equine species, are extremely rare in man. Only four of these are recorded. They have up to this time been noticed only in very advanced life, and chiefly in males. In the case published in this work there were tumours the size of cherries, which coalesced and formed a tumour the size of a man's hand, of blackish colour. The progress of these tumours is fatal, and the length of life does not exceed three years.

We have no space to notice further the admirably practical work of M. Nepveu. Suffice it to say that no ardent student of clinical surgery should omit to consult its pages.

THE DISEASES OF TROPICAL CLIMATES AND THEIR TREATMENT. (a)

This is an exceedingly difficult book to review. An abstract is impossible, and to express an opinion about it would not be fair to writer and reader without some explanation. The necessity for such a work is obvious; whether Dr. Horton was the man to write it is not quite proven by his book. There is much honest good work in it of which he may be proud; but it lacks much that it should contain. The strides of modern physiology have been gigantic of late years, and especially that portion of it which has to do with digestive assimilation and the function of the liver, matters of the most vital importance in reference to life in tropical regions. A man whose life has been spent in active service, and whose proof-sheets were corrected in the field in the Ashantee campaign, must have many allowances made for him. An extract from his preface will put him and his position very fairly before the reader.

"In collecting together my notes, and arranging them in the form in which I now present them to the profession, I have endeavoured to bring in also the opinions and experiences of the most able writers on the subjects of which I have treated, comparing them with one another, as well as with my own observations; and although I am painfully aware of the fact that there are many deficiencies and shortcomings in the work (more especially as the printer's proofs had to be sent out to the coast of Africa for correction, a great number of which were revised whilst busily engaged in the field in the recent Ashantee campaign), yet still I will crave their indulgence in stating that, in thus placing the accumulated facts before them, I have endeavoured to describe the diseases faithfully, both from my personal observations and from what I have obtained from the writings of others; and I hope that I have succeeded in giving much useful information in tropical diseases generally, and placing in the hands of young tropical practitioners a handbook of practical importance and utility in their early career."

There can be no doubt that for such young practitioners as are going out to tropical climates this work is one of great value. They will find in it the various diseases of tropical climates faithfully described; but there is something amissing. Dr. Horton has read much of older writers, knows the practice of the past, has seen the diseases he well pourtrays, but—well, I suppose we must remember that he has not sat in his study and read hard, and had to keep himself abreast of recent literature by hack writing. This, the second edition, dates from Cape Coast Castle, the first of January in the past year, and not from Marylebone, so we must make the requisite allowances. The fact that the first edition is dated, "Western Africa, October, 1874," is the best evidence of the appreciation of the work. Still when it is written, "opium is the most important and valuable remedy we have" in the treatment of cholera; when the use of calomel is discussed; when no reference is made to Prof. Geo. Johnson's researches, and the discussions which followed his advocacy of castor oil; when nothing is said about the treatment with belladonna; and Surgeon-Major A. R. Hall's experiences with hypodermic injections of chloral, which promise so much, we are doubtful as to whether the book is abreast of the times. When a writer on diseases of tropical climates is apparently unacquainted with the late Dr. Murchison's invaluable lectures on the functional disorders of the liver, we do hold the opinion that he can scarcely represent modern views, or avoid the feeling that the work represents the past rather than present medicine.

AMBULANCE LECTURES. (b)

This little *brochure* is the result of a course of Ambulance Lectures delivered to the Volunteer Corps, to which Dr. Weatherly is surgeon, and after that to the staff at the Bristol railway station. They were printed because he believes they may "form a useful work for the policemen, railway officials, and other men engaged in large works, as well as for the public at large." And that some such information, as is here

(a) "The Diseases of Tropical Climates and their Treatment; with Hints for the Preservation of Health in the Tropics." By J. A. B. Horton, M.D. Edin., F.R.G.S., Surgeon-Major of the Army Medical Department. Pp. 681. J. and A. Churchill, 1879.

(b) "Ambulance Lectures." By Lionel A. Weatherly, M.D., Surgeon to the 1st Gloucester Artillery Volunteer Corps. Griffith and Farran. P. 85. 1880.

furnished, should be generally known is certain enough. While the surgeon is being summoned something may be done; and it is by no means unimportant that that something shall be judicious and not injurious. How far it may be possible to spread such knowledge as is useful in cases of accident remains to be seen; but a large number of persons will read this little book with great interest, and be thankful to Dr. Weatherly for having written it. Whether he has done his work well or indifferently it is scarcely possible to say, for we have nothing with which it can be compared; our own impression being that he has succeeded capitally in his venture. He commences by saying, "The Order of St. John, under whose banner these lectures are delivered, is an order whose work, if properly taken in hand, must of necessity do good." We did not know that St. John had a banner, and should much like to know what the venerable saint did with it, and where it has been preserved since his time. However, it seems that the Order of St. John consists of a number of persons sincerely anxious to be of use to their neighbours. Of course this has great attractions for the order of busybodies, who will join anything that enables them to be fussy; but at the same time a number of sensible persons will be thankful for the information here furnished to them. Dr. Weatherly takes them over the structures and functions of the body, and puts them through a course of anatomy as regards the circulation, which will be stiff reading for some. He illustrates his subject by some capital original drawings, which add largely to the value of the book. He comes out strong on the intestines; a matter of small moment, we should think, in a work of this kind. What "Peyer's patches" and "Lieberkühn's glands" have to do with ambulance, we must confess we do not ourselves quite see; but that may be our obtuseness. He says, the "liver cells, besides secreting bile, also act upon certain parts of the blood, and turn them into sugar, but this process is not fully understood." Now this information may be all well enough for ambulance busybodies, but we think Dr. Weatherly needs a little more reading up about the relations of the liver to sugar, which it would be well for him to set about before he prepares a second edition; just for his own benefit. Then he gives clear and simple rules for the arrest of the different forms of hæmorrhage; how to fasten up a fractured limb; and what to do in cases of insensibility. He naïvely says, of opium-poisoning, "you must be almost brutal in your efforts to stop this sleep getting the better of the patient." Unless the Order of St. John possess rather more discretion than falls to the lot of ordinary persons, we can imagine a good deal of unkind treatment being exercised towards sundry unfortunate persons, under the sanction of this recommendation of Dr. Weatherly's. Then he describes what should be done in cases of drowning, suffocation, &c.; and finally, concludes with an excellent chapter on "bandaging, removal of injured or sick persons by bearers, stretchers, country carts, or by train." Dr. Weatherly has done his allotted work very creditably; has furnished a quantity of valuable information for sensible persons; and also given sundry busybodies a great treat in teaching them how to make themselves important in the disguise of humanity; for which no doubt they will be sufficiently thankful. The work deserves to be widely read, and is, decidedly, a "happy thought."

Medical News.

Outbreak of Cholera in Accrington.—An alarming outbreak of choleraic-diarrhœa was reported to the Accrington Town Council on Monday. Already there have been many deaths, and a large number of persons are suffering from the disease. Dr. Clayton informed the Council that the epidemic was caused mainly by people eating unwholesome food, and not by drinking the town water, as was commonly supposed. Instructions were given for necessary precautions to be taken, and a temporary appointment of a medical officer was made pending the approval of the Local Government Board. In the evening Mr. Johnston, an old member of the Town Council, died after only a few hours' suffering from the disease.

At the last examination of the King and Queen's Colleges, Ireland, Dr. Fanny Butler passed her final examination. She has taken the whole of her curriculum at the London School of Medicine for Women and the Royal Free Hospital, and will shortly leave for India to pursue her work as a medical missionary in connection with the Zenana Mission.

University of Glasgow.—The following degrees were conferred at the last meeting of the University Court:—

Doctors of Medicine, (M.D.)

Bryce, James, M.B.
Denniston, James, M.B.
Dun, William G., M.B.
Elder, George, M.B.
Gemmell, Samson, M.B.
Hunt, Thomas, M.B.
Hutchison, James, M.B.
Jones, James Arthur, M.B.
Young, Thomas, M.B.

Bachelors of Medicine and Masters in Surgery (M.B. & C.M.)

Adam, Alexander
Anderson, Matt. S., M.A.
Blyth, David
Bond, John
Boyd, James D.
Brown, John T.
Campbell, Walter Scott
Campbell, William A.
Davidson, Thomas
Dinsmore, George H. J.
Fraser, William
Gemmell, Thomas P.
Gilbert, Robert
Gilchrist, Robert M.
Grant, David
Gregson, Thomas W.
Gupta, Pyari Mohan
Hogarth, Andw. A., M.A.
Inglis, David W., M.A.
Johnston, Alexander
Jones, Wm. Rees
Kaye, James
Kerr, John G. Douglas
Kilpatrick, Alexander

NOTICES TO CORRESPONDENTS.

☞ **Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," 'Old Subscriber," &c. Much confusion will be spared by attention to this rule.**

Local Reports and News.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

Dr. Haughton, Norwood.—The gentleman to whom you sent your letters is on his holiday. In future please address "The Editor," not any member of the staff, in order to avoid delay. Unfortunately we cannot oblige you in this instance, as it is against our rules to insert correspondence provoked in another journal.

Mr. Street is thanked for drawing our attention to the paragraph in an advertisement. The advertiser's intention was probably not one of wilfulness to mislead, but of oversight. In any case our publisher requested its alteration, and it was at once granted.

Dr. Smythe, Indiana.—At any time if your copy fails to reach you, the publisher will forward a duplicate without charge, as the covers are sometimes torn off through the post. A second number of June 30 has been duly posted.

THE HYPODERMIC INJECTION OF PILOCARPINE FOR ASTHMA.

We are requested to state that the letter on the "Hypodermic Injection of Pilocarpine for Asthma," published in our last, and purporting to be signed by Dr. Carey, of Limerick, was not written by him, his signature thereto being a forgery.

Attendance on Constabulary.—We have submitted the question to the Inspector-General, and hope to publish a reply in our next.

Dr. Pearse, Plymouth.—Your paper "On Consumption" is marked for early insertion.

Mr. Newton, Exeter.—The non-acknowledgment of your communication was an oversight.

Dr. Passanha, Portarlington, will please receive our thanks.

Belfast.—We shall watch the development of this latest venture,

and not hesitate to speak out at the proper time. We fear there are one or two restless spirits in your city imbued with the undignified notions of those who, in English cities, are generally described as "quacks."

VACANCIES.

Aberdeen University.—Examinerships in Medicine. Full particulars of the Secretary.

Abingdon Union.—Medical Officer for No. 3 District. Salary, £130. Applications to the Clerk by Sept. 11.

Cambrige County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board. Applications to F. M. Francis, 17 Emmanuel Street, Cambridge, by Sept. 27.

Galway Union, Oranmore Dispensary.—Medical Officer. Salary, £120, with fees, &c. Election, Sept. 20.

Islington.—District Medical Officer for the Parish of St. Mary. Salary, £80, with the usual extra fees. Applications to the Clerk of the Guardians by Sept. 15.

North Dublin Union, Clontarf (No. 1) Dispensary.—Medical Officer. Salary, £150, with fees, &c. Election, Sept. 14.

APPOINTMENTS.

Ballance, C. A., L.R.C.P., M.R.C.S., House Surgeon to St. Thomas's Hospital.

Butler, H. P., M.R.C.S., L.R.C.P., House Physician to St. Thomas's Hospital.

Galpin, R., M.R.C.S.E., Medical Officer for District No. 6 of the Braintree Union.

Hatton, G. S., M.B., M.S., M.R.C.S., House Physician to St. Thomas's Hospital.

Hayward, J. W., M.R.C.S.E., Medical Officer and Vaccinator for the Whitstable District of the Blear Union.

Lawford, J. B., M.D., M.R.C.S., Assistant House Physician to St. Thomas's Hospital.

Lunn, J. R., L.R.C.P., M.R.C.S., House Surgeon to St. Thomas's Hospital.

McLearn, I. C., M.D., M.Ch., Medical Superintendent of the Highgate Infirmary.

Meller, C. M., M.D., M.R.C.S.E., Medical Officer of Health for the Carisbrooke District of the Isle of Wight Union.

Mills, S. B. A., L.R.C.S.Ed., Medical Officer to the Danaghmore Dispensary, Newry Union.

Newsholme, A., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital.

Palmer, B. A., M.D., Medical Officer to the Crossmaglen Dispensary, Castleblaney Union.

Richardson, C. B., M.R.C.S., L.R.C.P., Assistant House Surgeon to St. Thomas's Hospital.

Simpson, T., M.R.C.S.E., Medical Officer for District No. 5 of the Braintree Union.

Thomson, R. T. W., M.B., C.M., Medical Officer to the Alwinton District of the Rothbury Union.

Trimble, C. J., L.R.C.P.Ed., L.R.C.S.I., Medical Officer to the Fifth District of the Preston Union.

Vaisey, T. F., M.R.C.S.E., House Surgeon to the Bucks General Infirmary.

Walters, F. R., M.R.C.S., Assistant House Physician to St. Thomas's Hospital.

Births.

Finlay.—Sept 2, at 91 Montague Street, Portman Square, W., the wife of David W. Finlay, M.D., of a daughter.

Moloney.—Aug. 28, at Collconey, co. Sligo, the wife of John Moloney, L.R.C.S.I., of a son.

Saul.—Aug. 28, Fenton-Cawthorne House, Lancaster, the wife of W. Wingate Saul, M.D., of a daughter.

Saunderson.—Aug. 23, at Springfield, Philipstown, King's County, the wife of Robert Saunderson, M.D., L.R.C.S.I, of a daughter.

Marriages.

Macready—Davidson.—Sept. 1, at the parish church of St. Marylebone, Jonathan F. C. H. Macready, F.R.C.S., to Fanny Sarah, youngest daughter of the late James Davidson, of the Bengal Civil Service.

Phillips—Toms.—Sept. 4, at St. Abbott's, Kensington, George Bagster Phillips, M.R.C.S., of Norton Folgate, to Lizzie, youngest daughter of the late John Toms, of Chard, Somerset.

Renner—Beatling.—Sept. 2, at 80 Portsdown Road, Bayswater, Chas. Renner, M.D., to Emma, eldest daughter of Robert Bertling, M.D.

Deaths.

Hewett.—Aug. 29, at his residence, Southgate, John Dickason Hewett, M.D., only son of the late George Goodman John Hewett, Surgeon, R.N., aged 64.

Lawrence.—Aug. 31, at Benhall Vicarage, Suffolk, after a short illness, John Travers Lawrence, M.R.C.S.E., of Launceston.

Mitchell.—Aug. 31, at 21 Pepys Road, Hatcham, S.E., Robert Mitchell, Surgeon, formerly of Manor House, Deptford, aged 75.

Pritchard.—Aug. 27, at Crescent Lodge, Kingston, near Portsmouth, John Frederick Pritchard, Staff Surgeon, R.N. (retired), third son of the late Vice-Admiral Pritchard, R.N., aged 52.

Watson.—Sept. 3, at Oakfield, Reigate, Mary Watson, sister of Sir Thos. Watson, Bart., M.D., in her 85th year.

Williamson.—Aug. 3, at Grahamstown, Cape of Good Hope, John Edwin Williamson, M.D., formerly of Nantwich, Cheshire, aged 45.

WILHELM'S QUELLE WATER.

BEST NATURAL EFFERVESCING TABLE WATER,

FROM THE WILHELM'S QUELLE, AT KRONTHAL, NEAR HOMBURG.

"The Pearl of Table Waters."—*Morning Post.*

Dr. VON LAUER, Physician-in-Chief to H.M. the Emperor of Germany, and Surgeon-in-Chief to all the German Armies, says,—

"I can recommend the **WATER of THE WILHELM'S QUELLE**, at Kronthal, from my own personal experience as a most excellent and refreshing beverage. From the Analysis of the Water I consider that it would be most beneficial in stimulating the action of the mucous membranes, and its use in any affections of these latter in connection with the respiratory and digestive organs, would be attended with the best results."

"More delicate than either Seltzer or Apollinaris. A natural restorer of the essential Saline constituents of the blood."—See letter of Dr. HARLEY in *Lancet*, 7th June, 1879.

"Superior as a daily drink to the most approved Waters. It is just sufficient to develope the bouquet of the more delicate Wines, which is deteriorated by admixture with most Mineral Waters."—JOHN HARLEY, M.D., *Physician to St. Thomas's Hospital.*

☞ **THE WILHELM'S QUELLE WATER** is noted for its purity and pleasant flavour, and also mixes admirably with Spirits, Wines, or Milk. It is a powerful Tonic, and is recommended for Indigestion, Gout, Rheumatism, Heartburn, and many Diseases of the Liver and Kidneys.

THE WILHELM'S QUELLE is the only Natural Sparkling Table Water which has been found to contain Iron in the same form as that contained in the Human Blood, viz., "The protoxide of Iron." It acts therefore as a Tonic instead of being weakening and depressing, obviating thereby the principal objection many eminent Medical Men have to the constant use of all other Mineral Table Waters.

SOLE IMPORTERS:

THE WILHELM'S QUELLE COMPANY, LIMITED,

7 BILLITER SQUARE, LONDON, E.C., AND 101 PRINCES STREET, EDINBURGH.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

SOME OBSERVATIONS ON CONSUMPTION.

By WILLIAM H. PEARSE, M.D. Edin.,

Physician to the Plymouth Public Dispensary.

There is no phenomenon in natural history more arresting to the mind of the medical observer than the access of phthisis; that, *e.g.*, a young man or woman shall enjoy health and strength, up to a certain age only, after which the lung structures shall cease to be healthily evolved or developed, followed by the death of the individual, within a year or two, opens problems in the natural history of man's relationship to all physical and vito-physical existences of the widest kind. Advanced as are our chemistry and physics, under the great developing theories of the correlation of force and continuity, and advancing as is our method in the study of vital phenomena, under the grand generalisation and hypothesis of evolution, and widening as are our generalisations on vital being, as necessarily related in series, and in true "continuity," with the inorganic forces or energy, not the less no mind has yet arisen capable of grasping the varied phenomena in their true relations to the deviations of rate or growth, the so-called diseases: in the great variety of known physical and vito-physical conditions, which we see are related to phthisis, no mind has yet grasped the "crucial or commanding instance" which shall give light.

In the present paper I make no attempt at such generalisation, but simply record some facts as seen in practice, but stated in connection with their fairly related ideas.

Not the less, it may be well to remember, that the simplest and commonest facts are parts of the greatest "universals," and no one can predict which fact, in any domain of nature, shall convey the "illuminating idea," as Coleridge expresses it, which shall give light on our method. We are thus justified in recording any facts or phenomena which have "relation of circumstance" in those who pass into phthisis, and this in the hope of approaching nearer the knowledge of a potential co-ordination of the vital power or energy against the passage into phthisis.

For some years past I have kept a record of some of the more prevailing and typical peculiarities of those phthisical patients whom I have seen, in the hope that some law or determinate series might appear, either in the anatomical peculiarities, or in the deviations of function, or in both. Since 1876, over four hundred phthisical cases, in different stages, have presented; and although, at first, I did not note functional symptoms, or physical peculiarities of the body, but the physical signs of the chest, and treatment only, not the less, what observations were recorded may be of interest and value.

Skin System.—Teeth.—The upper incisors (whether right or left not specified) were decayed in 92 of those "delicate;" in the same class of "delicate" an additional 13 had the left upper incisor gone, 6 had the right upper incisor gone, or a total of 111. In the same class of "delicate" and earlier stage of phthisis, the upper incisors were sound in 19.

In decided phthisis the upper incisors were decayed (right or left not specified) in 22 cases; in addition to these are noted 2 of phthisis of right lung, with right and left upper incisors gone; 1 of decided phthisis of left lung, with right and left upper incisors gone. In addition to these, 5 had the left lung diseased and all the upper incisors gone; 2 had the right lung diseased, and all the upper incisors gone; 1 had both lungs diseased and some right and left incisors gone; thus, in decided phthisis, 33 had diseased upper incisors. In 22 cases of decided phthisis, the enamel is noted as extra white and translucent, and with decayed upper incisors. This type of enamel presented far oftener than the number indicates; many were not noted. In addition, the right lung was diseased and right upper incisors in 4 cases, the right lung diseased and left upper incisors in 2 cases, the left lung diseased and left upper incisors in 4 cases, the left lung diseased and right upper incisors in 4 cases. Thus 69 cases of decided phthisis appear, with associated decay of the upper incisors; but the proportion is really greater, as I did not, in earlier cases, record the state of the teeth.

In 10 cases of decided phthisis the upper incisors were of extra white enamel, and were not decayed; in 2 cases of decided phthisis of both lungs the upper incisors were not decayed; in 13 cases with phthisis of right lung, and in 4 with phthisis of left lung, the upper incisors were not decayed.

In phthisical cases the upper incisors are often beyond the average size.

The upper incisors were decayed, in 10 cases, classed under bronchial type of phthisis.

In 2 cases of phthisis the upper middle incisors were extremely large; in 7 the upper lateral incisors were abnormally small; in 1 the upper middle and lateral incisors seemed inter-changed in position; in 3 the enamel was yellow, and furrowed vertically; in 1, the two upper middle incisors were large, and projected forward. (This case, seven years ago, had well-marked physical signs of phthisis at the top of one lung, but is now a healthy sound woman.) Three "delicate" cases had yellow enamel with vertical furrows. In a few "delicate" cases the lower incisors were decayed.

Canine Teeth.—In decided phthisis the right upper canine and left lung were gone in 2 cases; the right upper canine and right lung in 1; the left upper canine and left lung in 1. Both upper canines, together with the upper incisors, were gone in 10 "delicate" cases; the right upper canine only gone in 1 delicate case. The lower canines were decayed in 4 cases of phthisis.

These observations on the teeth and phthisis are far too limited to have statistical value, nor are they enough to indicate, with exactness, the law or series of relationship that exists between lung and teeth evolution, growth, and healthy sustention; but it is obvious that a co-relationship (*a*) exists in man's body between the evolution or vital energy of those nerve segments, of which the lungs, teeth, and skin system, are respectively differentiated parts.

To the practical physician the type of bright enamel, with spots of lateral decay, which usually precede the lung disease, will direct his attention to pursuing early in cases, the best hygienic modes of life for warding off phthisis, and the avoidance of those varied depressions which tend to develope phthisis.

Co-relation exists in other parts of the skin system to phthisis; heavy eyebrows, which tended to meet in the middle line, were noted in 32 cases; this type presented oftener than the fine pencilled eyebrow.

The hair may be very fine, but is often coarse, and in large amount; the skin may be unusually downy, as also exquisitely fine; the whiskers, in young men, may be well-developed, but are often downy, thin, and straggling.

The nails show varied types: the fine almond-shaped nail is most common, but many had large flat nails. Both in early and advanced phthisis I have often noticed that the fore-finger nail was the only one clubbed.

Bone System.—In the consumptive the nose often tends more than is normal to one or other side. In those "delicate" and in earlier stages of phthisis, the nose tended to the right in 21 cases; to the left in 14. In cases with advanced phthisis of both lungs, the nose tended to the right in 4; to the left in 1. In cases where the nose tended to the left, the left lung was most diseased in 8 cases, the right lung in 3 cases. In cases where the nose tended to the right, the right lung was most diseased in 9 cases; the left lung in 10 cases. The nose was mesial, but depressed at the bridge in a few cases. The terminal cartilages of the nose are often peculiar, being in some pinched in, laterally, but prominent at the end; in 13 cases the terminal cartilages were large and lumpy. These peculiarities are apart from that generally prevailing stillness and want of action of the alæ nasi, which is seen in the phthisical, involving, as must this latter, a deficient nerve power in the general respiratory system.

(*a*) The word co-relation is used in the sense of Darwin; correlation in the sense of Grove.

The hands may be small and delicately shaped, but a considerable proportion presented unusually large and cold hands.

In a few the thorax and infra-clavicular regions were full and well developed.

In many cases, not only the nose, but the supra-maxillary bone itself, as seen in the great lateral obliquity of the upper incisor teeth, is abnormally lateral.

In the history of our knowledge, both of the inorganic and organic worlds, alterations, or apparent irregularities, or eccentricities have been those phenomena which have most powerfully led to a recognition of general laws, and it cannot be without profound interest in studying the Form of phthisis to see this disease corelated with the evolution of the osseous and nerve systems.

Seeing the prevalent immobility of the infra-clavicular regions in the phthisical, it seems important to train the young to breathe through the nostrils rather than through the mouth. Expansion of the thorax and elevation of the infra-clavicular regions is much promoted by closing the lips and breathing by the nostrils. Such a habit, carried on throughout the years of growth, would aid much in developing the vigour of the thoracic regions.

Of the thirty cases in which inquiry was made, twice as many fathers died of phthisis than mothers, and twice as many brothers than sisters.

Hereditary syphilis, as shown by typical upper incisors, presented in one case only.

Diet.—I have in a former paper mentioned the frequent desire of phthisical patients for onions, salted and smoked fish, &c. Of those asked, forty had a great desire for onions against eight without such desire. Twenty-six desired pickles and vinegar against four who did not. I cannot avoid again remarking on the frequency with which onions are debarred young delicate people and phthisical patients. It is a continually recurring experience with me to hear young people say how great is their desire for onions, and which are often preferred raw, eaten with a little salt; and it is rarely that I have heard that onions disagree.

I conceive that it is of the greatest importance to follow Nature's lead in the matter of the appetite; nascent states of combination and powers exist in Nature's own productions, which no present chemistry can analyse or imitate, and as phthisis is a slow deviation or failure of vital formative energy, so we may, with great reason, seek to supply conditions of food which Nature indicates. The living fauna of any country is the necessitous result of its physical condition; prior forms of plants and animals disappear in geological periods, and future forms are evolving with present progressive physical conditions. Such is the delicacy of relation of life and animal forms to physical conditions, and such the power of the slightest but continuously acting variation in physical surroundings, to modify species and genera of plants and animals. And these broad general truths apply to man and his deviations or diseases with equal force. His vital formative energy being maintained, not only by full external physical conditions, but by food also, his desires for special natural foods have as much foundation in law as has the seeming selection of a particular *habitat* by classes of plants and animals.

I conceive, further, that a marked passion for a special food, such as that of the phthisical for onions, puts us on a right path toward further knowledge. We are not content now to rest in approximative statements that certain foods or minerals do good to the system; but we are certain that, in unison with the great truths of evolution and continuity, such therapeutic good must depend on certain precise physical or vito-physical conditions. To a right method of study, analogy may show us further discovery long before analysis may be able to demonstrate the exact physical relation.

On these grounds, and with these hopes, I continually ask those delicate and in phthisis if they have any special desires for food. That supplying those delicate and in phthisis with certain foods which are much longed for,

does not realise all our hopes of arresting the disease, should not surprise us, when we remember that the animal body is, as the Chinese say, a "microcosm of the universe," and is in true and absolute correlation with all physical existences.

Functional Symptoms.—Of those asked 29 habitually suffered cold feet at night to 5 who did not; it is a very marked symptom in many. Those who had the privilege of studying under the late Prof. Alison, will remember the interest with which he used to relate the experience of two large children's schools in Edinburgh, in one of which many died of phthisis, whilst the other was free from this disease. The one and determining circumstance of difference in the two was, that in the healthy school the dormitories had fires, before which the children were accustomed to warm themselves before going into bed. In the other the children went to bed cold, and complained of remaining cold during the nights. It was amongst the latter that phthisis prevailed. It is important to recall attention to this symptom. I often see young people "delicate" and in phthisis, who for many years have suffered from cold feet at night, but who have had no precautions taken against it. I never omit to order the use of hot jars or hot fire bricks, wrapped in flannel, to be placed in the beds of children and young people, who suffer from cold at night, and advise their use throughout the whole period of growth. The symptom is not only of great import practically, but has its place and suggestiveness physiologically. The symptom must form part of that general, long-continued, varied, and involved series of deviations from health, or depressions of power, whose termination is phthisis.

Out-of-door life.—I am well aware that cases can be made to establish any proposition; but if there is one thing more than another forced on our attention here in this rather depressing south coast, it is the immediate and great good which delicate and early phthisical patients get to their general vigour, appetite, and health, by a change to out-of-door life on Dartmoor, or on the north coast. It is a popular saying that "people don't take cold on the moors."

Just as on the side of certain foods and drugs when good follows their use, we seek in them the more exact and limited facts from which this result follows, so in the great good which follows change to out-of-door life and moorland air we seek to know the more exact correlations of force, or parts of the atmosphere which produce the result. The practical physician gathers up the facts and experiences of what climates in the world are most free from phthisis, but he looks to the scientific chemist for the knowledge of the exact physical composition of the atmosphere, and for the knowledge of those correlations and states on which sustained vital energy and health depend.

Holding it to be a "necessary truth" that life and living beings are an evolved and an evolving series, and related to all physical existences, we may expect our means of preventing phthisis to be reached not only by the physician's study of climates, but by the studies of the comparative naturalist and physiologist, unfolding the rates and order of the evolution of the different parts of the living animal; as *e.g.*, the relation of the lung segments to the skin and osseous system; and yet further by the chemist showing us on what correlated modes of energy or force vital being is most nearly in continuity; we may fairly seek to learn the rate or expression of that geometric series on and with which living being is evolved; and in the vast mass of facts now accumulating in chemistry, physics, in organic mathematical analysis, and in the observation of the varied conditions under which phthisis appears, we may fairly hope that a generalisation will soon appear which shall help us toward more exact modes of giving the bodies of those who tend to phthisis such vital energy as shall sustain the longevity of the lung segments, to the greater ongevity of the other segments and organs of the body.

SYPHILITIC INSANITY. (*a*)

By C. R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S. Eng.,

Senior Physician to the Metropolitan Free Hospital of London; Physician to the Rescue Society.

If we consult most medical men of great experience in the treatment of syphilis, the chances are that some of them will say that they have not come across any cases of syphilitic insanity. One well-known writer on syphilis, Dr. Lewin, of Berlin, indeed, declares that whilst he has treated at the Charité Hospital of that city more than 20,000 venereal patients (12,000 women and 8,000 men), not one per cent. of these became insane, and among these small number not one was paralysed. Syphilis, then, apparently does not frequently give rise to insanity. But to say, as some do, that insanity is *never* due to the syphilitic virus is, in my opinion, as great an error.

Before the year 1860 it was almost a heresy to say that syphilis was capable of causing disease of the brain or spinal cord; and, indeed, it was generally looked upon as a surgical disease, *i.e.*, one which concerned entirely that division of the profession who concern themselves chiefly with diseases attacking the outward parts of the body. This opinion has been abandoned, and everyone of experience now knows that syphilis very frequently causes some form of paralysis, especially of the cerebral nerves.

In the great majority of cases where syphilis attacks the brain, it injures also the intellect, and sometimes mental affections are the very first symptom of the brain lesion. These mental affections are divisible into those of slow evolution with depression, and those with delirium or mania. Of the former many will admit that they have seen examples. The latter form is less generally admitted by alienists and syphilographers to come within the limits of syphilis. I have seen several instances of this cerebral syphilis with depression, loss of memory, and dementia.

Case I.—Thus, a gentleman, who contracted syphilis in 1869, became in the course of two years, irascible, slightly ataxic, deeply depressed, and gradually entirely unfit for active life. He lost his memory, shunned his friends, then had epileptiform seizures, gradually became demented, and died comatose.

Case II.—In another case seen in 1864, a patient who had been for some years affected by syphilis, and who had no family history of insanity, but had been steady and temperate, became infected with the mania of persecution, refused to speak, and died in a lunatic asylum. I believe that in certain cases where suicidal tendencies are very strong, there is present some form of cerebral syphilis, which causes a fit of delirium now and then. Many patients, I am convinced, have been looked on as common lunatics with maniacal excitement, when they were merely syphilitic patients with delirium.

Case III.—In 1879 I was treating for an obstinate secondary eruption a young man, æt. 28, with the family history of whom I was acquainted. He did not come to see me for three months; and on next seeing me he complained that he had been put in a lunatic asylum by his parents. Suspecting the nature of the case, I asked him to send his relatives to call on me, and then ascertained that he had been seized with a maniacal fit, which made it dangerous to have him at home. He was, therefore, placed for a month in an asylum, and for some time was fed by means of the stomach tube. He then recovered perfectly, and resumed his business, which he had, for a time, entirely neglected. This is the kind of case which is usually styled syphilitic insanity; and it has more than once been in my experience to see such a case.

Case IV.—Dr. Alfred Fournier mentions a case where a man, æt. 30, syphilitic three years, had vertigo and diplopia, followed by delirium, with loquacity and somnolence, which passed into furious mania. Mercury and iodide of potassium cured him at once. It is impossible

(*a*) A paper read before the British Medical Association, 1880, Annual Meeting, Cambridge.

in many cases to distinguish syphilitic mania from ordinary mania. It has been said that the mania from cerebral syphilis is less tumultous, violent, and mobile than ordinary mania.

Case V.—The great syphilographer, Ricord, believed firmly in syphilitic insanity. He mentions a case where a gentleman lost his memory and intellect for a month, and was durin g that time pronounced insane. He recovered under specific treatment. Zambaco also mentions a case where violent headache was the precursor of epileptic fits which, for a time, were amenable to treatment. Next ensued furious mania for four days, and the patient then fell into dementia, with loss of memory and hallucinations.

Cases of a similar nature have been narrated by Dr. B. Tuke, Dr. Broadbent, Dr. Grainger Stewart, Dr. Wilks, Dr. Buzzard, and Dr. Hughlings-Jackson.

When a patient has some evident symptom of syphilis, such as skin eruption, or paralysis of the motores oculi present, it is not difficult to make the diagnosis in a case of syphilitic insanity. The main difficulty lies in these cases, when insanity comes on in a syphilitic patient who has had very slight symptoms of the action of the poison. In such cases we can only consult the friends, and, if possible, it is useful to speak to those friends who have been most intimate with the patient, and who are likely to have been informed as to whether there is any chance of syphilis having existed. Of course, although insanity is hereditary, people may often become insane from other causes, such as alcohol. It is well, however, to remember the possibility of syphilis being a cause of mania, and even go the length of administering mercury and iodide of potassium for a short time in doubtful cases, since the number of cases of curable insanity has been augmented already since the idea was first admitted that syphilis might occasionally cause it.

General paralysis of the insane has been supposed by some authors to be occasionally caused by syphilis of the brain; but I cannot believe that such can be the case, although certain German authorities are very affirmative on the point. It is true, perhaps, that many patients with general paralysis have had syphilis. Mendel, a German physician, speaks of 90 cases out of 176; but there are many reasons why it is difficult to admit that there is any relation of cause and effect in these two diseases. General paralysis has very marked characters; it is almost confined to the male sex, scarcely ever seen before the age of 35, and, in the male, it almost always affects the middle classes, whilst, in women, it almost always is seen amongst the poor. Syphilis, as we know, has no preference for either age or sex, and when the cranium of a patient with cerebral syphilis is opened, we never find (as in the general paralytic invariably is the case) generalised meningitis. Cerebral syphilis presents us with partial lesions. The affection of the cranium in general paralysis never goes beyond the meninges; whilst in the case of gummy tumour commencing in the meninges, it will extend and attack either the dura mater, the bones, or the cerebral pulp itself. If it has lasted long, we cannot say where it began.

Treatment again is of great service in many cases of cerebral syphilis, sometimes restoring apparently hopeless case. When general paralysis exists, all treatment is unavailing. Specifics have no power at all against a meningitis, which, if it were syphilitic, should surely be affected by them.

Many cases, too, are on record, where syphilis has coexisted with general paralysis of the insane. In such cases specific treatment can remove an exostosis, or a paralysis of the motores oculi, or a gummy tumour in the palate; but it leaves the other affection untouched.

Hence my conclusion is that syphilis has nothing to do with the general paralysis of the insane. We hear of tuberculosis of the lungs co-existing with gummy tumour of these organs, and, in the same way exactly we may find in the cranium of the patient who succumbs to general paralysis of the insane, generalised meningitis side by side with syphilitic disease of the arteries or meninges. But this seems to me to be coincidence, not causation.

I conclude syphilitic insanity exists, as mania, melancholia, or dementia; but not in the form of the general paralysis of the insane.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Œsophageal Obstruction.

(Under the care of Dr. DYCE DUCKWORTH).

Thomas B——, æt. 58, was admitted to St. Bartholomew's Hospltal on Aug. 6. He stated that about the beginning of December last the solid part of his food appeared to pass over some obstruction. In the middle of January he became unable to swallow meat. Since experiencing the difficulty in swallowing he had occasionally coughed up a little blood.

On trial, it was found that he could, with great difficulty, swallow a small piece of bread which was given to him.

On percussion, an area of impaired resonance was found, extending for 2 or 3 inches on each side of the spine in the upper dorsal region.

Ausoultation showed the breathing over the area of dulness to be bronchial.

It was found that obstruction existed to the flow of blood in the left jugular vein, which could only be emptied with difficulty. Finally, a moderate-sized bougie was passed down the pharynx; after reaching a point, 11½ inches from the teeth, it met with some obstacle, and it was deemed unsafe to force it farther.

The patient was much emaciated. He was ordered milk-diet, 2 eggs, 2 oz. brandy, and custard-pudding. The following notes indicate the subsequent history:—

Aug. 9th.—Fair night. He finds he can swallow much better than he gave us to understand, being able to eat soft-boiled eggs. To have tinctura quiniæ ammoniatæ, 1 drachm, three times a day, and a linctus.

10th.—To have 20 minims of tr. stramonia, and 2 drachms of syr. papaveris.

14th.—About 9.30 p.m. last night, he had a sudden attack of dyspnœa, which lasted about three-quarters of an hour; it came on suddenly while he was asleep. After the attack there was a copious expectoration of thick mucus. He had never experienced a similar attack previous to this. There is tracheal breathing along the sternum, and an area of dulness between the scapulæ on the left side of the spinal column, with vocal vibration and bronchial breathing increased over it. Emaciation increased. To have nutrient enemata.

16th.—Passed a fair night. Breathing much shorter. The attacks of dyspnœa and expectoration continue, and the phlegm is increased. He can't take so much food as at first. He is weaker and more emaciated.

On the following morning the patient died of asthenia.

A post-mortem examination was made with the following results:—

In the œsophagus, beginning about 2 inches below the cricoid cartilage, and reaching 5 or 6 inches down, was a deposit of grey matter, soft, and ulcerated on the surface, and infiltrating the walls and neighbourhood of the œsophagus.

The trachea and aorta were adherent to the œsophagus. At the back of the trachea, just above the bifurcation, the abnormal growth sprouted into its interior. Just at the commencement of the descending part of the aorta was an atheromatous patch, causing a transverse crack in the inner coat. The outer coat, however, was not involved.

The bronchial glands were somewhat enlarged and highly pigmented, the lungs highly pigmented and very œdematous.

In the upper lobe of the left lung was a round patch of new growth of a grey colour, in transverse section the size of a sixpence; it was well-defined from the surrounding healthy lung tissue. The microscope revealed the cancerous nature of the growth in the œsophagus, which was seen to consist of cells of a lympho-sarcomatous type.

Second Case of Œsophageal Obstruction, due to Cancer.

(Under the care of DR. DUCKWORTH.)

WILLIAM B. R., æt. 44, salesman, was admitted to St. Bartholomew's Hospital on August 13, with the following history:—

He had suffered from winter cough for four or five years, but otherwise enjoyed good health until last March, about which time he contracted a bad cough, lost his appetite, and began to lose flesh. In June he began to have difficulty in swallowing. He left his work about a month ago.

On admission he was much emaciated. Nothing abnormal was discovered about his larynx and œsophagus above the sternum, nor in his mode of swallowing. His chest was emphysematous; no cardiac dulness being discoverable. There was dulness at the right apex, and the right side of the chest was seen to expand less than the left. The breathing was coarse, and expiration prolonged. The pulse was 60, hard and full; temperature normal.

He stated that his powers of swallowing varied very much; sometimes he could hardly get a drop down, sometimes he could drink freely, but was at all times unable to swallow solids, and generally had a bad fit of coughing after swallowing anything.

He was put on a liquid diet, and ordered hydrocyanic acid in ℥v. doses every six hours.

August 16th.—Has passed a fair night. Swallows very badly; any attempt to swallow produces a fit of coughing, with expectoration of a large amount of frothy sputa. Dulness at both apices behind; the right being duller. Breathing sounds on right side, in front, bare bronchial. There is absolute dulness behind in the interscapular region, with bronchial breathing, more especially on the right. Nutrient enemata ordered.

17th.—Not so much cough. Can swallow better. Finds he can sip iced milk without causing a fit of coughing. Temp. 100·8.

18th.—Passed fair night; swallows better; enemata retained.

The patient now appeared to be rallying, but in a day or two symptoms of a new character appeared; his temperature rose to 101° on the 21st, to 101·5° on the 23rd, and 103·3° on the 25th, and he was evidently wasting. Stimulants and tonics were administered, but to no purpose, and the patient died on the 31st at 2·30 p.m.

The post-mortem appearances were as follows:—In the right pleura, near the head of the eighth rib, was a roughened yellowish patch, of the size of a threepenny piece, covering both surfaces. The œsophagus was normal down to the bifurcation of the trachea; from this point an ulcer reached nearly to the diaphragm; its edges above and below were raised, the healthy tissue terminating abruptly. The surface was foul. The ulcer caused a stricture, through which a director failed to pass. The walls of the œsophagus were thickened by the new growth, which was soft and friable. On the right side it invaded the lung, and apparently extended into the small bronchi. The trachea and bronchi were intact, but the right bronchus was filled with a friable substance. Almost all the lower lobe of the right lung was gangrenous.

THE annual rates of mortality per 1,000 last week in the large towns of the United Kingdom were—Oldham 19, Plymouth 19, Edinburgh 20, London 21, Bristol 22, Portsmouth 22, Brighton 23, Birmingham 23, Bradford 24, Newcastle-upon-Tyne 26, Hull 27, Manchester 27, Sheffield 27, Leeds 27, Wolverhampton 27, Liverpool 34, Nottingham 35, Salford 35, Norwich 35, Dublin 36, and the highest rate 38 in Sunderland and Leicester.

Translations.

THE PHILOSOPHY OF SLEEP AND DREAMS.

By M. DELBOEUF.

Translated from the *Revue Philosophique*,

By EDWIN JACKSON, B.A., M.R.C.S.,

Manchester.

PART I.

CRITICAL SKETCH OF SOME RECENT WORKS.

III.

(*Continued from page* 199.)

THE work of M. Radestock, which appeared a little after that of Spitta, is conceived in the same spirit, but the author takes his stand more on the physiological side of the question, and occupies a great number of pages in setting forth the importance of dreams in studying the psychology of different races.

This book, dedicated to Professor Wundt, is interesting, full of facts, written clearly and methodically, and easy to read, but it is by no means free from digressions.

It comprises six chapters. The first is taken up with the influence of sleep and dreams on individuals as well as on nations: here we find collected the different opinions which ancients and moderns have expressed with regard to dreams. "They form an important constituent in the belief of the immortality of the soul," and the part they play in political history is by no means a slight one; it is enough to mention the Oracle of Delphi, the visions of Mahomet, the hallucinations of Joan of Arc.

In the following chapter M. Radestock cites the numerous definitions which poets and philosophers in all ages have given of dreams. Then, unfolding his views on the nature of the union of body and soul, "which are only different aspects of one and the same thing," he thence urges the necessity in the study of dreams of not devoting ourselves exclusively to psychical phenomena to the neglect of those of the body. The third chapter is devoted to the "reproductive faculty, normal and abnormal." Everything in nature changes—the soul as well as the body—but the past is found linked with the present by memory. Reproduction may take two forms: according as the newly-found image is or is not as vivid as the original there is *hallucination* (illusion) or *recollection*. Reproduction has its root in the association of ideas, the laws of which are well known—the laws of similarity, of contrast, of co-existence, and of succession.

M. Radestock, following here the example of most psychologists, does not seek out the ultimate principle of these laws. Ideas do not simply follow one upon another; they are sometimes connected together, and are united in the same way as sensations are interwoven. It is thus that the image of a hatchet, recalling that of wood and of a carpenter, and, uniting with them, forms the compound image of a man occupied with cleaving wood. The difference between recollection and hallucination depends on the force of the excitement; between the two there is every imaginable grade. Hallucination is a reproduction which has a brilliancy comparable with that of the reality; the principal factor in the illusion, then, is necessarily an exaltation of the excitability of the central nervous system. I note in passing that this explanation is no explanation at all; it is pure hypothesis; the unknown cannot serve to elucidate the obscure. I will add that the conclusion does not strictly follow from the premisses; the illusion might proceed from an enfeeblement of the peripheral nervous system. As to the definition of hallucination, it has some truth in it, but it certainly is incomplete; the example quoted by the author in support of his hypothesis is calculated to show this insufficiency. Brierre de Boismont tells of a painter who could produce a portrait of a person whom he had only once seen, and one which should be very like him. The number of times adds nothing further to the work. I ask if the artist who sees from memory an absent person with a keenness such that he can exactly reproduce his features, is under the dominion of an hallucination? Evidently not. Something more is needed. The subject must be the plaything of an illusion, and must attribute to the object which is entirely in himself an

external existence present, even when his reason tells him that he is in error.

M. Radestock is thus led rapidly to review the different excitants of the nervous system—stramonium, belladonna, hachish, &c.; then starvation and the alterations in the organs of the senses. On this difficult subject words undoubtedly often take the place of ideas, and nerves and cells, the brain and spinal cord crop up oftener than they should. In spite of this criticism, I can state with pleasure that all this portion contains sober and substantial *résumés*.

We come at last to the definition of a dream: it is the "*continuation during sleep of the activity of the mind.*"

Aristotle says a dream is properly the image produced by sensible impressions when we are in a sleep, and so far as we are asleep. This definition is infinitely preferable, and I will say further that it has not been surpassed. A feeble hearing of the crow of a cock when we are asleep is not dreaming, says Stagyritus, for this hearing is the act of the mind which is awake, and not of the mind which is asleep. Nothing more true. Every activity of the mind during sleep is not necessarily a dream. I do not dream when towards morning, though still asleep, I indistinctly hear the noises in the house, or in the street; but I dream if I think I am taking part in a conversation which does not take place. From this it follows that the definition of a dream is subordinate to that of sleep. I will return to this important point later on. It is particularly of sleep, of its causes, and its peculiarities, that the following chapter treats. Speaking of the causes which favour or promote sleep, such as quietness, the position of the body, &c., M. Radestock quotes experiences which contradict M. Preyer's theory. We know that this distinguished man has maintained that sleep was due to the presence of an "exhaustion material" analogous to lactic acid, and produced by fatigue. He has consequently studied the effects of the introduction of this latter substance under the skin or into the stomach, and he thought that he had proved that it produced sleep. It would appear, according to M. Lothar Meyer, that these effects are far from constant. As to a physiological explanation of sleep, the author affirms that none exists, and that he will not attempt to give one; he will content himself with showing its physiological effects; they are sufficiently well known for me to pass them over in silence. As to its psychological effects, they are much more matter of dispute; some authors maintain that during sleep consciousness is suppressed, others retain it. The illustrious Fechner has quite an original opinion on this subject. According to him, at the moment when we fall asleep consciousness attains its point of nullity, and when we are fast asleep it acquires a negative value. I have, in some former articles (*a*), criticised "negative sensations," as the father of psychophysics has defined them sufficiently for there to be no need to linger over the still stranger notion of a negative consciousness. M. Radestock, in view of settling the question, like M. Spitta, makes a distinction between self-consciousness and simple consciousness. The former is suppressed, but the latter remains, for every representation is necessarily conscious, for were it otherwise it would be nothing but a simple "disposition" (Wundt). For my own part, I have never arrived at a clear understanding of what is meant by self consciousness, as opposed to simple consciousness. I could better understand the expression "non-self-consciousness." I should thus designate the faculty, indispensable to every sensible being, in virtue of which he attributes to something outside of himself the cause of his affection. We should thus distinguish in the phenomena which are passing within us, those of which we have no consciousness, those of which we have consciousness, and those which are accompanied by "external consciousness." But the time has not yet come for me to pause over the principle of this distinction.

There is no complete opposition between waking and sleep. In sleep the psychical activities are softened but not abolished; indeed, however life-like may be the images of our dreams, they are duller and darker than those of our waking moments. We may then formulate this conclusion: in profound sleep, just as the organic and vegetative functions are depressed, so is the psychical activity reduced to a minimum without being completely suspended.

The fifth chapter treats of the "Elements of Dreams;" it is one of the best and most complete in the whole book. We find here an examination of the effects of sensorial and organic impressions, and their transformation into dreams; and also the part which memory plays in them.

However, as I do not gather any really new ideas from it, the analysis which I have already given of Dr. Maudsley's work, which treats of the same subject, will save me the necessity of lingering any longer over it. There would, however, still be many interesting studies that might be undertaken in that direction.

There can be no doubt that many of our dreams are only the dramatisation of impressions received during sleep; thus, people who accidentally or habitually experience an uneasiness in breathing, dream about narrow passages or ceilings falling in, caverns or catacombs, a crush in a crowd, or carriage-poles driven into the chest—in a word, all scenes in which we are suffocated or are short of air. The connection is evident. Then following out these comparisons we should in all probability arrive at a physiological classification of dreams, and at the same time at a classification of real acts from the point of view of their action on our organism, through the medium of the mind. (*a*)

The next chapter, which I am about to epitomise, has for its object the pointing out of the difference between the dream and the waking thought. This is a matter of the greatest importance, as I have already remarked, and should be one of the chief points in every theory of dreams and of sleep. M. Radestock treats it with his usual learning and acuteness. Although the problem might, it seems to me, be more condensed, still the pages in which it is discussed are almost all excellent, full of observations that are true if not profound, and form a very satisfactory and thoroughly connected whole.

I must acknowledge that I have rarely read anything on the subject which has given me more pleasure. Let me add that the argument is always plain, simple, and expressed in a clear, easy, and natural style.

A dream is mobile and changeable; nothing more common than to see a cat transforming itself into a girl, a tree into a church, in a dream. I should like, however, to express my own doubts as to these pretended changes. I ask myself whether they are true changes. When we relate dreams of this kind we never say that the cat was changed into a young girl, the tree into a church; we express ourselves differently. For example, "I was playing with a cat, but a moment after it was no longer a cat, it was a young girl;" or again, "I was at first under a tree, but without my knowing how, I found myself in the middle of a church." Well, then, in my opinion we have first dreamt about a cat, then about a young girl; and it is our minds which, it may be during sleep, it may be and more frequently is on awakening, in order to explain the continuity of certain other parts of the dream, supposes a change which we have not expressly experienced in our dream; in fact, there would be a simple substitution of one image for another without any internal and progressive change. These few words are enough for the present, and I pass on.

The dream is full of vivacity and exaggeration; whence can this proceed but from a change in the circulation of the blood which exalts the irritability of the central nervous system? Still a hypothesis and not an explanation. The author adds, however, that the feelings experienced during sleep never have the intensity of those which move us during our waking moments. People may die of joy, or of fear, but there is no instance known of a dream causing death. (*b*)

I believe that this restriction would apply exactly to the images themselves of the dream whose vivacity, in my opinion, is entirely relative.

The dream developes without any intervention of the will. This proposition, true, generally speaking, is perhaps too absolute. I dreamt one morning about one of my friends who had been married for a considerable time, but only before the civil authority; for some reason or other, contrary to his known principles, he thought—so I dreamt—that he ought to have the union blessed by the priest. There must on such an occasion be a procession; the announcement had roused the whole community, and curious like the rest I went to the

(*a*) See this Review, March 1877 and February 1878.

(*a*) Not that there is any lack of attempts at classifications of dreams, but either they are arbitrary in their details, or they rest on distinctions of sentiment or of language (agreeable or disagreeable dreams, historical dreams, prophetic dreams, &c.).

(*b*) Still, I have heard that a young person who was known to my family had one night so terrible a dream that her hair, from being black, quickly became perfectly white.

church, wishing particularly to see the countenance of the husband. I crushed through the crowd, and managed to get into the front row. Still the procession did not come; while waiting I thought of all sorts of things, to kill time. Impatience, at last, took possession of me, and at the same time I had a distinct feeling that I was about to waken. I heard the usual morning noises about the house, but wishing by all means to be present on the arrival of this procession, I *made several attempts* to fall asleep again, and to complete my dream *as a dream*. They were of no avail, and I awakened in spite of myself, without having been able to satisfy my curiosity. This dream seems to me calculated to confirm what I previously stated; self-consciousness is the explicit perception of the reality as such, so that in sleep there would always be consciousness, be it ever so slight, for we cannot imagine our ever being entirely separated from the reality.

The dream is the creator of new combinations; but its products rarely have any value; its inventions are almost always pure absurdities, like those of the madman. There is, then, in sleep a weakening of the faculty of judging and of reasoning. We quite naturally see hussars exercising on the ridge of a house-top; or we cross the Alps after Hannibal. These peculiarities arise, according to the author, from spontaneous associations and assimilations, in which the law of resemblance plays the chief part; as also the link which unites certain bodily impressions with the ideas which they ordinarily call forth.

Often also in dreams the phenomenon known as *self division*, or *dédoublement*, manifests itself. We attribute to another our own thoughts and feelings. To the examples already known I wish to add another, extremely complete in all its relations.

One evening at a gathering of friends, among other subjects of conversation, I introduced this question of *dédoublement* of the person. I related the remarkable case of Van Goens, who, when a boy at school, and ambitious of always being at the top of the class, dreamt one night that the master gave him a Latin sentence to translate. Van Goens could not manage it; but this did not trouble him so much as did seeing one of his schoolfellows make signs, which showed that he had caught the meaning. The master had in the end to ask this pupil, and he translated the passage without making the slightest mistake, and thus gained the first place. This dream was the subject of some remarks, and then we talked about something else. Our conversation turned to the time when people had been very much interested in threatenings—afterwards realised—that Mount Etna had for some time been giving forth. That same night my friend, Professor Spring, who has a peculiar faculty of clever dreaming, took it into his head—so he dreamt—to seek out some means whereby he might be enabled to foretell the eruptions some time beforehand. We can at the present time in some measure foretell storms, and describe their probable progress; and why should we not try to do the same with regard to volcanic phenomena? The comparison in itself was good. But M. Spring in vain ransacked his brain; he gained nothing. Then he makes up his mind to go and consult a *savant* of his acquaintance—he does not know whom—about it. He goes to his house, happily finds him at home, and tells him his difficulty. His friend at once grasps the idea, and in a moment furnishes him with the desired solution. It would only be a question of inserting into the ground at different points some thermo-electric needles, connected one with another, and with a central point, in order to be made aware of the approach of the currents of lava. M. Spring very much approved of the idea, and went back home, amazed at the facility of conception displayed by his friend, the *savant*.

Here is M. Radestock's explanation of this remarkable case. According to him it owes its origin to the enfeeblement of one of the elements of self-knowledge. Self-consciousness includes the gathering together and attributing to the same subject of a certain number of ideas, sentiments, volitions, and recollections, and in addition, attention and active perception. During sleep this latter factor is annulled, and the former only remains. The man then is conscious only to a limited extent; he no longer regards himself as the sole author of his ideas, and he attributes a part of them to others.

This appears to me to be a description rather than an explanation of the fact. For my part I am inclined to recognise only the putting into action of that habit of thought which works in the form of a dialogue. At the moment of writing, I converse with an imaginary reader; and when I do not myself think distinctly, and am myself in doubt, I attribute to him objections and doubts. I might quite as well take up his position, and put into his mouth the answers and solutions. I simply point out this idea, my purpose not being to compose a complete treatise on dreams.

(To be continued.)

Special.

LOCAL CONDITIONS IN RELATION TO ENDEMIC DISEASES IN INDIA.

In the study of that large class of diseases—namely, such as are endemic—by which the ranks of our forces in India are yearly thinned, two important points present themselves, one comprising the general influences upon which the origin of these affections ultimately depends; the other those conditions of locality which tend to fix, in some instances, to intensify them in nearly all, in particular places, when they have been brought into activity. With regard to the first of these points very much remains to be effected before it can be said that our actual knowledge has got beyond the rudimentary stage; but in so far as conditions of locality are concerned, attention has of late years been so much directed to them that general influences, as they affect individual systems and diathesis, it is to be feared run some little risk of being insufficiently thought of. Surgeon-Major F. N. Macnamara, M.D., (*a*) in his very valuable work has paid careful attention on both these points, and we have been at a good deal of pains to arrange some of his observations with regard to them, so as to admit of ready reference. Thus:—

Localities.—In Purneah, certain *thanas*, or sub-districts, are described as unhealthy (232); in Bhangalpore others are similarly described (235). In Tirhoot there are unhealthy parts in the north and north-east of the district, although generally the district is healthy (240). With regard to Oude, the statement occurs in reference to the prevalence of malarial fevers (279) that the sanitary condition, state and repair of wells, comfort, &c., of the inhabitants of the villages in which it occurred were precisely circumstanced as the rest of the district, namely, those in which it did not prevail (300). On the other hand, with regard to Dhera, the statement occurs that in every instance some local cause about the dwellings of the patients could be discovered sufficient to account satisfactorily for the illness (306). At Chuckrata, 5,000 to 7,000 feet high, the occurrence of ague takes place, although the want of subsoil and surface drainage can scarcely be a principal factor in its causation; the prevalence of that disease at such an elevation is not easily accounted for (336). At Mooltan, where drainage is bad, excessive rainfalls or excessive inundations are almost invariably followed by extraordinary sickness among the people (353). In the Punjab, bowel complaints in connection with fevers are found to prevail in localities of the most opposite characters in point of soil, humidity, and altitude; but they have one special *period* in common, in which they flourish altogether, independent of sanitary conditions of locality (355). Nor is it alone with regard to fever that this is the case. Dr. Cutcliffe states in reference to the epidemic of cholera which spread from Hurdwar in 1867, that it did not extend among the people after the pilgrims had returned to many of the filthy places which he describes, places in which were every conceivable abomination of polluted soil, and air, and water (300). Elsewhere, however, a connection was traced between the occurrence of fever and local conditions; thus, in Chunparun bad remittents especially affect the inhabitants of the very dirty town of Ramnuger (247). Certain places have the character of unhealthiness, such

(*a*) "Himalayan India, its Climate and Diseases." Longmans, Green, and Co., London. 1880.

as Mean Meer (54); Kuloo is unhealthy in consequence of natural conditions, including damp soil, rich vegetation, and hot sun (390). But on the other hand, in the valley of the Gaomuttee, near Almorah, the forest is not very dense, and yet, for some unexplained reason, that tract is unhealthy to a degree (315). From these circumstances the conclusion seems natural that so far as the observations go, the precise relation, between the conditions of the places named, and the diseases alluded to, has yet to be definitely laid down.

Cultivation.—In Oude, cultivation of particular crops did not appear to exert any influence on the prevalence of fevers (279).

Water is a medium in which *malaria* accumulates (47). In many instances cholera is directly traceable to the use of impure water; but "neither in Bengal nor elsewhere in India can we connect periodic fluctuations in the prevalence of cholera with fluctuations in the degree of impurity of the drinking water of the people" (119). Foul water is a fertile source of dysentery, diarrhœa, and of round worms (136). In Tirhoot, where there is stagnant water, the people suffer from fever; but not always, nor are we able to explain the cause of this difference (240). At Simla, the foulness of the water, added to malaria and *chill*, occasions the diarrhœa which prevails there (383). At Peshawur the water of the canal is foul and infected, but inasmuch as the Europeans and some of the native troops use the uncontaminated water of certain wells, this condition can be counted but as a partial factor in the unhealthiness of the station (462). At Bunnoo, drinking water is taken from open gutters, and from tanks fed by gutters; it is no wonder that the men suffer terribly from fever, enlarged spleen, and diarrhœa (471). The circumstance is in accord with experience in India that persons whose system is saturated with *malaria* acquire a peculiar and characteristic dark complexion; according to native belief, the water of the Ghuggur, containing malaria from irrigated lands, renders their skins dark (366). It would appear then from the above that although water is a medium of *malaria*, and a cause of certain local affections, the relation between its condition and the prevalence of those diseases is not always the same.

Canals and Irrigation.—In the Rohilcund terai irrigation was looked upon as hurtful to the health of the people (287). In the Doab, epidemics of malarial fevers prevailed before canals were constructed (302). In the Punjab, unless they intercept the natural drainage, canals were themselves innocuous (354). Although in some instances fever seemed to prevail most in places under the influence of canal irrigation, there were others—as the Khadir of the Jumna—not under the influence of canal irrigation, where fevers prevailed with an intensity as great as in the worst of the canal villages (371—410). In the Baree Doab, malarial fevers prevailed before the system of canal irrigation was introduced, although fever may have been increased since that system was brought into use (410—417). Fever is increased when the surface is overflowed; not otherwise (*id.*) At Mooltan, canals were looked upon as a factor, although a minor one, in causing fevers (489). In 1877 an outbreak of malarial fever took place at that station, although practically there was no overflow from rivers or canals (491), but on an island in the Chenab opposite Midh the inhabitants suffer comparatively little from fever and dysentery (490). The general result therefore appears to be, that although under certain circumstances the presence of canals and irrigation increases the prevalence of malarial fevers, they do not in all instances, or necessarily do so.

Malaria.—Does *malaria* simply express the result of certain *climatic influences*, or does it imply the existence of something material, a poison? (46). The former has the support of some observers (*id.*); that *climatic influences* may suffice to explain many attacks of fever would, no doubt, be generally admitted (*id.*); but the hypothesis which attributes malarious diseases to a specific miasm is that which best accounts for their phenomena (*id.*). The discovery of the *Bacillus Malariæ* in the air and soil of the Ager Romana is announced (*id.*); but "we know nothing of the nicer circumstances which are needful for the generation of the poison" (*id.*). One is struck in reading medical reports by the very frequent and often matter-of-course way in which *chill* is spoken of as the cause of fever in India. It is needless to assume the existence of specific malarial poison; let a person be predisposed by fatigue, or by the results of long-continued residence in a hot and damp *climate*, and then a *chill* may produce an attack of fever; but in *malarious* countries we have often to treat fever in people who have not been exposed to chill nor any other condition apart from *malarial* poisoning (48). If *malaria* is a mere expression of the effect of *climatic* causes on the system, paroxysmal fever ought to prevail in all localities where there is a marsh, with hot and extreme *climate*, and occasional chilling winds; but we by no means find malarial diseases in all places where every condition seems favourable for their development. We often find malarious fever prevalent in very equable climates, and at the most equable season of the year (49). Malarious poisoning appears more frequently at the end than at the beginning of the warm season (51). The term *climatic* is applied to the ordinary autumnal fever of the Punjab (70); also to a group of diseases by which the greatest part of the mortality in India is occasioned (91). These are intermittent and remittent fevers, and their sequelæ, dysentery, diarrhœa, cholera, and ill-health; also goître, and a low form of pleuro-pneumonia (396). In Assam, non-Aryan races are believed to suffer from its effects in a less degree than Aryans (166); and in the Oude terai, the Tharoos, a people who inhabit patches of cultivation there, are able to withstand the *pestilential climate* of that tract of jungle (268). With regard to Tirhoot, Dr. Mackinnon writes that "where we have stagnant waters and rank vegetation we often have fevers, but not always; nor are we able to explain why there is this difference." He observed that some of the lakes or lagoons were far more unhealthy than others (240). Malarial influences may precipitate themselves upon certain organs, producing apparently purely local disease, or local disease and anæmia, but without fever (247). With reference to the application of the terms *malaria* and *climate*, the statement occurs (275) that the *climate* of Gonda is considered very *malarious*; also (319) "there can be little doubt that the local conditions, whatever they are, which rendered *malarial* diseases more common at Petoraghur than at Lohoo Ghat, caused the greater prevalence of goître at the former station." Besides that affection, however, there are others which are considered directly due to *malaria*, an intermittent and remittent fever, dysentery and diarrhœa; between ague and the two latter, as they occur at Dhurumsala, there is considered to be a strong bond of connection (401). Adverting to the theory of *chill*, the remark occurs that "chills may dispose persons to fever, but it is difficult to believe that chills of an almost rainless and dewless August at Mooltan can account for outbreaks of fever (492). The effects of malaria are less prevalent in walled cities than in country districts (375); but persons whose health has been impaired by malaria in the plains are thereby rendered more liable to attacks of severe diarrhœa on going to some hill stations, as, for example, Dugshai (384). It is stated that under the malific influences of *malaria* and *climate* the health of prisoners at Peshawur becomes slowly sapped (461). Thus it would appear that uncertainty and differences exist in regard to the precise sense attached to the expression *malaria*—namely, as to whether it means "the result of *climatic* influences," something material, or a *chill*. According to the theory of marsh *miasm*, it is stated that although fevers often prevail where "we have stagnant waters and rank vegetation," yet such is not invariably the case, nor are we able to account for this difference.

Climate.—See also *Malaria.*—It is stated of the district of Sealkote that the district generally is very healthy; no *climate* in the world can be finer (419); yet that in July and August the *climate* becomes very *malarious*

(421). The *climate* of Jhelum may be said to be a very healthy one (423). With regard to Peshawur, we read of "the trying nature of the climate" (462), of which, like that of Assam, humidity is at its maximum; for hours there is scarcely a perceptible movement of air; the temperature at 91°, almost unbearable (*id.*), and yet conditions of *climate* do not alone appear to constitute a cause sufficient to account for the almost universal prevalence of autumn sickness among men and officers (463). The *climate* of the Dooars in Eastern Bengal is considered dangerous throughout the year (185); that of the district north of the river Vol, very *malarious*, that to the south, healthy (275); of the other portions of the district, pestilential (*id.*). Thus, while *climates* are alluded to as malarious, healthy, unhealthy, and pestilential, yet "conditions of climate do not alone appear to constitute a cause sufficient to account for the almost universal prevalence of autumn sickness." There is needed a factor in addition; the actual nature of which is here left unstated.

Residence and Acclimatisation.—It is stated that "every corps arriving at Buxa seems to have to undergo a sort of acclimatising process, the result of which is, that though in the first year the men are exceedingly unhealthy, yet during the second and succeeding years this unhealthy condition assumes much milder proportions (220). At Peshawur the residents do not suffer so severely from fever as do strangers coming among them; the native regiments suffer less in their second and third year's stay in the station than the first; yet it is not clear whether this comparative exemption from fever is due to the men having become accustomed to the climate, or to the weakly members having died or been invalided the first year (460). The results of these remarks appears to be that although residence in a *fever* locality renders a person less liable than at first to actual attacks of fever, a process of deterioration of general health progresses among those so exposed.

To be continued.

FRANCE.

[FROM OUR OWN CORRESPONDENT.]

At the meeting of the Societé des Hôpitaux, M. Hallopeau read a paper on the treatment of typhoid fever and erysipelas by salicylate of soda. In twenty cases did he employ the salicylate of soda and with satisfactory results. M. Hallopeau could not explain its effects upon the morbid contents of the intestine, but one thing was certain, and that was it lowered the temperature. Liebermeister, who especially employed this agent in typhoid fever, considered it as an anti-pyretic and anti-zymotic. In his statistics he gives but eleven per cent. as the mortality rate, which is very favourable. This is how he proceeds: He gives on the day of entry of the patient twenty-four grains of calomel, afterwards cold baths according to Brand's method, and then alternately sulphate of quinine about fifteen grains daily, and sulphate of soda in doses of two drachms. Under the influence of this treatment the temperature fell quickly. As Liebermeister, Dr. Hallopeau gave the calomel the first day, but he did not employ the cold baths but in exceptional cases; but he gave alternately sulphate of quinine and salicylate of soda, giving a drachm of the latter daily; this amount he found sufficient. Several objections were raised against the employment of salicylate of soda, the principal of which was based on its toxic effects. One hears of ulcerations of the pharynx, diarrhœa, &c., but this reproach was not founded. To avoid all accidents it is only necessary to dilute the medicine sufficiently. According to Dr. Hallopeau, salicylate of soda is contra-indicated in the thoracic and hæmorrhagic forms of typhoid fever.

At the same Societé M. Vallin presented a patient attacked with leprosy. This patient was sent to him from Cayenne with the diagnosis locomotor ataxy. He had, it was true, a certain unsteadiness in his gait, and extreme cutaneous sensibility, but further M. Vallin could not trace the supposed disease. At the end of three weeks that the man was under treatment spots were observed on his body, which M. Vallin, suspecting them to be leprous, examined closely for *baccilles*, and found some. Last year the patient was living on intimate terms with a young negress, who was attacked with leprosy. M. Rendic thought that the most striking fact in the last observation was the contagion. He had seen at the Hospital St. Louis a case of leprosy in a soldier. The man had lived three months at Haiti in a cabin with a family, one of whose members suffered from a similar affection. M. Besiner declared that some months ago leprosy was not considered contagious, but opinions are inclined to change. The question has not been studied scientifically. M. Vallin asked what should be done with his patient; should he be isolated? M. Besiner replied that, as regards this disease, medical science was not advanced enough to impose isolation. He had seen several cases at the St. Louis Hospital, but no case of infection was signalised. He considered that it required, as in scabies, a prolonged and intimate nocturnal contact. The patient that he had actually under his care was taking twenty drops of phenic acid daily without inconvenience, and the disease was progressing as fairly as could be expected.

In an article upon cystitis, published in the *Dictionaire Encyclopédique*, M. Chauvel recalls the advice given by M. Diday in the treatment of inflammation of the neck of the bladder. Drink three or four times a day an infusion of linseed mixed with pearl barley, rub into the lombar region antimonial ointment until an eruption takes place; resist the desire to evacuate the last drops of urine, and to take three times a day one of the following powders:—Sugar in powder, ℥ss.; hyosciamus leaves in powder, ʒss.; divide into 20 powders. If the pain persisted, M. Chauvel would give every half hour a tablespoonful of an infusion of 45 grains of hyosciannus leaves in ℥iv. of water. In a few hours there is almost always relief. If the toxic effect of the medicine manifested itself coffee was the antidote. In chronic cystitis the author obtained good results from the following preparation, of which about the size of a cherry stone would be given morning and evening in a wafer. Turpentine ℥ss., camphor gr. xv., ext. hyosciamus gr. iij.

A Russian doctor writes to the *St. Petersburgh Medical Gazette* on the "Utility of Chloral in Phthisis." In every case he had administered it he never had had the slightest accident. Sleep had been always calm. The physical symptoms were less evident in the morning; the patients felt themselves better and stronger; never did they complain of headache. When the chloral was suspended insomnolency appeared. The author sums up with the following conclusions:—Chloral, as an hypnotic is, by no means, indicated in phthisis. In the dose of from 15 to 30 grains it cannot do any harm, except in the last stage. It always procures refreshing sleep. It diminishes the sweating, and checks the losing of weight. It lowers the temperature, increases the urinary secretion, and does not produce headache, nor disturb the digestion.

Dr. Peuteves, in the *France Médicale*, recommends in order to render cod-liver oil tasteless, to mix a tablespoonful of it intimately with the yolk of an egg, add a few drops of essence of peppermint, and half a tumbler of sugared water, so as to obtain a *lait du poule*. By this means the taste and characteristic odour of the oil is entirely covered, and the patients take it without the slightest repugnance. Besides, the oil being thus rendered miscible, as the water in all its proportions is in as complete state of emulsion as the fats at the moment they penetrate the chyle vessels, consequently absorption is better assured.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 20, Bombay 31, Madras 33; Paris 26; Geneva 31; Brussels 34; Amsterdam 29, Rotterdam 19, The Hague 29; Copenhagen 32; Stockholm 21; Christiania 28; St. Petersburgh 39; Berlin 29, Hamburg 31, Dresden 26, Breslau 34, Munich 26; Vienna 21, Buda-Pesth 38; Turin, 24; Venice, 22; New York 29, Brooklyn 25, Philadelphia 19, and Baltimore 17 per 1,000 of the population. Small-pox caused 49, and typhoid fever 31 deaths in Paris.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, SEPTEMBER 15, 1880.

THE UNIVERSITY OF ST. ANDREWS.

ON the 26th of July last Sir Trevor Lawrence asked the Home Secretary whether his attention had been directed to the embarrassed financial position of the United College of the University of St. Andrews, and whether he would take any steps to relieve the College from the pecuniary difficulties in which it found itself involved? The answer which this question elicited from Sir William Harcourt was of an encouraging description. He said the Government would consider the subject during the recess, and would state early next session any proposals they had to make with regard to St. Andrews University. We should have preferred an intimation that the immediate necessities of the University were to be promptly relieved, but the present Government has set its face resolutely against supplementary estimates, and we must be content to wait, therefore, until February next for what we cannot doubt will be a practical solution of the pecuniary difficulties of this ancient and deserving institution, coupled, perhaps, with conditions as to its future operations, on which Parliament will deliberate.

The misfortunes which have befallen St. Andrews University cannot be said to reflect any discredit upon her. Like many a private individual in these days, she is the victim of bad harvests and American competition, not in those intellectual commodities in which she traffics, but in corn and beef. The farms from which her sustenance has been chiefly derived—for the fees paid by her pupils and graduates are but a small item in the income of this remote and cheap seat of learning—have turned out unproductive. The rents of some of them have been materially reduced. Percentages have had to be returned to discontented tenants, and a few farms have been left vacant, and have been carried on at anything but a profit by the University itself, for it has been found that a Principal, with a knowledge of pastoral poetry, is not necessarily the best guide in practical agriculture, and that mathematics affords no insight into the feeding properties of oil-cake. Under these circumstances the emoluments of many of the professors have been seriously diminished, in some cases to two-thirds, and in others to one-third of what they previously were. As the St. Andrews Professors never at the best received more than a scanty pittance, their condition is now truly deplorable. They have to maintain the position of gentlemen with the allowances of artisans, and have to teach literature and science when perplexed by the most elementary problems of domestic economy. They are entitled to public sympathy, and what is more to the point, to public support, for St. Andrews University is a national institution, and it would be a national disgrace to leave it, borne down by petty cares and pecuniary anxieties. As the oldest of the Scottish universities, it might have set up some claims of primogeniture, but this it has never done, having modestly abstained from urging its rights and requirements even when rich bounties were being bestowed upon the younger universities. The Professors in the other universities have had their incomes largely increased during the last quarter of a century, while those in St. Andrews have had their incomes docked more than once. The most recent exaction to which they have been subjected has arisen out of an ordinance of the University Commissioners requiring them to set aside between £600 and £700 annually in payment of debts contracted by their predecessors in office, before a penny of the present revenue accruing from the College lands is divisible amongst them. This implies a deduction of about £70 per annum from the income of each of the Professors in the United College, who are being further mulcted in arrears of tithes, with compound interest thereon, underpaid to the Crown long before any of the present incumbents held office. No supplementary estimate is required to suspend these payments for a time until the position of the University can be thoroughly inquired into, or to transfer their incidence to the University chest from the pockets of the sorely-oppressed Professors of the United College.

But whether or not any measures of temporary relief are adopted, a scheme of permanent amelioration must certainly be prepared. We cannot allow the professors in one of our universities, even although they bear their grievances quietly and patiently, to struggle on with incomes miserably inadequate and far short of what they were told they might reasonably expect when they

IRISH POOR-LAW INTELLIGENCE.

MEDICAL ATTENDANCE ON THE ROYAL IRISH CONSTABULARY.

A QUESTION has been put to us whether the medical attendant of a Constabulary station is liable to attend the wife, father, sister, and children of the sub-inspector; a case being quoted in which such attendance (and the medicines necessary) had been asked for and given by the medical attendant. The answer is not very easy. In the official regulations which set forth the duty and emoluments of the medical officer ("Irish Medical Directory," page 316), a distinction is made between "members of the Constabulary on duty," and the "men" who have wives and families. By Article 1, the medical attendant must attend all the former class, which undoubtedly includes the sub-inspector. By Article 2 he is also obliged to attend "the wives and families of *men* stationed in the district." Our reading of these regulations is that the medical officer is not called upon to take charge of the families of anyone above the rank of a constable, sub-constable, or serjeant.

Desiring to confirm or refute our own view, we propounded the question to the inspector-general's office, at Dublin Castle, by whom we are informed that a reply will not be given to us, but that "if a sub-inspector or "medical attendant of the Force requires information on "the subject, and applies for it officially, the inspector-"general will endeavour to satisfy the applicant." We must, therefore, refer our correspondent to the office at the Castle.

HE VITAL STATISTICS OF IRELAND FOR THE PAST QUARTER.

DURING the quarter ended 30th June last there was registered in Ireland a birthrate of 26·2 in every 1,000 of the estimated population; and 28,715 deaths, representing an annual rate of 21·6. In the same period 49,032 persons emigrated. A decrease of 42,778 would therefore appear to have taken place in the population.

In England the birth-rate was 36·6, and the death-rate 19·7 per 1,000.

The birth-rate for Ireland during this quarter is under the average rate for the corresponding quarter of five years by 1·6 per 1,000 of the population.

The death-rate is 1·9 above the average; it is 1·3 under that of the preceding quarter. The apparent proportional increase would be more than accounted for by the improved registration consequent on the burial returns furnished under the Public Health Acts.

The returns of pauperism show a large increase in the number of persons receiving relief, as compared with the corresponding quarter of 1879 and with the past ten years.

The birth-ratio registered during the quarter was 26·2 per 1,000. Thus the birth-rate was 1·6 per 1,000 under the average.

The respective rates for the four provinces last quarter are—Leinster 27·0 per 1,000 persons, Munster 28·4, Ulster 25·5, and Connaught 23·3. The highest county birth-rate is 32·1 per 1,000, for Dublin, and the lowest 20·4 for Mayo.

The deaths during the quarter amount to 28·715, or 21·6 per 1,000 of the estimated population, against an average five-year rate of 19·7.

In considering the apparently increased death-rate it must be taken into consideration that the registered deaths have been considerably increased, probably to the extent of ten per cent., by the information contained in the burial returns, forwarded to the registrar-general and the registrars under the Public Health (Ireland) Acts, 1878-79.

The death-rate in Leinster was 24·5, in Munster 20·3, in Ulster 22·0, and in Connaught 18·1.

The county death-rates range from 17·0 in Mayo to 32·7 in Dublin. Between these rates the lowest five are:—Sligo 17·4; Wicklow, 17·5; Galway, 18·1; Meath, 18·5; and Roscommon, 18·9; and the highest five are:—Louth, 25·3; Antrim, 23·0; Longford, 22·9; Armagh, 22·9; and Monaghan, 22·7 per 1,000.

In Leinster the total deaths are 4·7 per cent. above average. In Munster the deaths are only 0·3 per cent. above average. In Ulster the deaths are 11·9 per cent. above average, being considerably above the average in every county in the province. Compared with the corresponding quarter of 1879, there is a considerable increase in the total number of deaths in the province; and in Londonderry alone, of all the counties, is the number of deaths lower, and in that county by only one. In Connaught the deaths are 10·1 per cent. above average, being above in all the counties of the province.

HEALTH OF THE PEOPLE.

The registrar's notes appended to this report point to a steadily-growing interest on the part of those gentlemen in the sanitary improvement of the country, as the information supplied is more copious than heretofore. Although the death-rate is above the average, yet it is but slightly above the rate of the corresponding quarter of the year 1879. The comparative increase would be more than accounted for by the burial returns, and consequent increased accuracy of registration. Judging, therefore, by the registration returns it would not appear that there has been any material increase of disease or any extensive epidemic outbreak. An examination of the registrars' notes shows considerable prevalence of whooping-cough, scarlatina, and fever. With regard to fever, it appears that in the great majority of instances which have been noted the cases were few in number, and extended over but small areas, in many cases being confined to single houses or families.

Diseases.—The number of deaths returned by the registrars as having resulted from the principal zymotic diseases is 10·7 per cent. of the total deaths registered. This number of 30·3 per cent. over the deaths from the same causes in the corresponding quarter of 1879, and 21·2 per cent. over the average of three years.

Small-pox caused 182 deaths, against 94 in the preceding quarter. Of these 158 were in Leinster, 1 in Munster, 23 in Ulster, and none in Connaught. Of those which occurred in Leinster, 137 were in the county and city of Dublin (130 in the city). Of the 23 deaths in Ulster 10 were in the county of Antrim, 13 in Fermanagh.

From the foregoing statement it appears that the continued and increased fatality of small-pox in Ireland is almost altogether due to the persistent prevalence of that disease in Dublin, where it has been constantly present for the last three years.

Measles caused 266 deaths, against 361 in the preceding quarter, and compared with 183 in the corresponding quarter of 1879. Of these 98 were in Leinster, 103 in Munster, 50 in Ulster, and only 15 in Connaught.

Of the 98 deaths in Leinster, 86 were in the county and city of Dublin (73 in the city). Of the 103 deaths in Munster 48 were in the county and city of Cork. Of the 50 deaths in Ulster 31 were in the county of Antrim (25 in Belfast), 11 in Donegal. Of the 15 deaths in Connaught 11 were in the county of Mayo.

Scarlatina caused 570 deaths, against 610 in the preceding quarter, and compared with 307 in the corresponding quarter of last year. Of these 257 were in Leinster, 192 in Munster, 109 in Ulster, and 12 in Connaught.

Of the 257 deaths in Leinster, 174 were in the county and city of Dublin (123 in the city). Of the 192 deaths in Munster, some occurred in each county of the province; 85 were in Cork, 44 in Tipperary, and 31 in Waterford. Of the 109 deaths in Ulster, 50 were in the county of Donegal, 35 were in the county of Tyrone.

Diphtheria caused 68 deaths, against 76 in the preceding quarter, and compared with 74 the corresponding quarter of 1879. Of these, 23 were in Leinster, 19 in Munster, 21 in Ulster, and 5 in Connaught.

Whooping-cough caused 612 deaths, against 554 in the preceding quarter, and compared with 416 in the corresponding quarter of 1879. Thus this disease has increased in fatality. Of the deaths from whooping-cough, 174 were in Leinster, 122 in Munster, 281 in Ulster, and 35 in Connaught. Of the deaths in Leinster, 120 were in the county and city of Dublin.

Fever caused 877 deaths, against 788 in the previous quarter, and compared with 744 in the corresponding quarter of 1879. Of these deaths, 230 were in Leinster, 273 in Munster, 212 in Ulster, and 162 in Connaught. The returns show that under the general term "fever" the numbers have increased in Leinster by 41, in Munster by 47, in Connaught by 43, and have diminished in Ulster by 42, as compared with the previous quarter. Of the 230 deaths from fever in Leinster, 137 were in the county and city of Dublin (96 in the city).

There were 683 inquests reported to the registrars during the quarter, this number being equal to 1 in every 42 of the total deaths registered. In Leinster there was 1 inquest to every 34 deaths registered; in Munster 1 to 40; in Ulster 1 to 49; and in Connaught 1 to 51.

Of the 28,715 deaths registered during the quarter, 4,482, or 15·6 per cent., occurred in public institutions. In Leinster the percentage was 20·7, in Munster 20·4, in Ulster 10·1, and in Connaught 10·9.

The average number of persons in Ireland receiving in-door relief on Saturdays during the second quarter of 1880 was 55,790, against 51,332 for the corresponding period in 1879. The average weekly number of persons receiving out-door relief during the quarter was 63,890, against 48,070 for the second quarter of 1879. Of the persons receiving in-door relief during the second quarter of 1880 an average number of 702 in each week were located in asylums for the blind and the deaf and dumb, and in extern hospitals; in the corresponding quarter of 1879 the average weekly number was 687.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF AUGUST, 1880.

AUGUST 5th—Palmer, Benjamin Armstrong; Roxborough, co. Armagh; M.B. Univ. Glas. 1880, Lic. R. Coll. Surg. Edin. 1880.

6th.—Johnston, James Alfred; Wesport, co. Mayo; Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel.. Lic. R. Coll. Surg. Irel. 1880.

7th.—Matthews, Thomas; Annahilt, Hillsborough, co. Down; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

7th.—Kerrigan, Owen Patrick; Mullingar, co. Westmeath; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

9th.—Fottrell, William Joseph; 70 Kenilworth Square, Rathgar, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

10th.—Harkness, Alexander; Coilt Mara, Cultra, Holywood, co. Down; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

10th.—Lacey, Thomas Samuel; 4 O'Sullivan Terrace, Ballybough Road, Dublin; Lic. R. Coll. Surg. Irel. 1878.

12th.—Digan, Matthew; O'Brien's Bridge, co. Clare; Lic. R. Coll. Surg. Irel. 1879, Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel.

12th.—Manning, George Henry; Ballyhaise, co. Cavan; M.B. 1879 and B.Ch. 1880 Univ. Dub., Lic. Mid. K. Q. Coll. Phys. Irel. 1880.

13th.—Mahon, Henry Greenwood; 18 Effra Road, Rathmines, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

13th.—Hamilton, Archibald Alexander; Thornhill, Dungannon, co. Tyrone; M.B. 1880 and B.Ch. 1880 Univ. Dub.

16th.—Fergusson, James Hugh; Gweedore Hotel, Letterkenny, co. Donegal; Lic. R. Coll, Phys. Edin. 1880, Lic. Fac. Phys. and Surg. Glag. 1880.

17.—Connelan, Abraham Sandys; Joanna Ville, Crumlin, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

20th.—Moylan, John Barry; Waterfall House, Richmond, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

21st.—Ledwich, Edward L'Estrange; 23 Upper Leeson Street, Dublin; Lic. R. Coll. Surg. Irel. 1878.

23rd.—Barrington, John Leslie; 7 Beechwood Avenue, Ranelegh, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

25th.—Gainfort, John; 3 Lower Sackville Street, Dublin; Lic. Apoth. Hall Dub. 1880.

28th.—Corcoran, Thomas; Collooney, co. Sligo; Lic. R. Coll. Surg. Irel. 1880.

30th.—Ottley, John; Keel Desertserges, Bandon, co. Cork; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

31st.—Moloney, Denis; Brosna, co. Kerry; Lic. Apoth. Hall Dub. 1879, Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

31st.—Baker, Richard John; Braemore, Balbriggan, co. Dublin; Lic. 1879 and Lic. Mid. 1880 R. Coll. Phys. Irel., M.B. Univ. Dub. 1880.

The following name has been restored to the Register, per order of Council, August, 1880, viz.:—

Feb. 1st, 1868.—Evans, Robert Locke; Grosvenor Place, Carrickfergus, co. Antrim; Lic. 1867 and Lic. Mid. 1867 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1867.

ABUSES OF MEDICAL RELIEF.

Dr. Ridley, of Tullamore, favours us with a list of tickets which he has caused to be cancelled at the last meeting of his committee. The list includes two "scarlet-runners" to visit at distances of three and five miles at the houses of farmers holding respectively 15 and 7½ acres. The remaining tickets on the list—18 in number, were for dispensary relief. Nine of them were invalid—the applicants residing outside the district. The other nine were for the families of farmers holding from 10 to 30 acres, and obviously well able to pay the doctor.

If every Poor-law medical officer in Ireland would follow Dr. Ridley's example, even for three months, we should soon see an end to the monstrous abuses of pauper relief in Ireland, and an immediate and substantial increase in the earnings of Poor-law medical officers throughout the country.

CORRESPONDENCE.

SUPERANNUATED MEDICAL OFFICERS AS J. P'S.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Can a superannuated medical officer of a dispensary, who is made a county magistrate, become an *ex-officio* guardian of a union. He is receiving £60 a year from the union pension.

Yours, &c.,

Nemo.

[We believe that no person who receives emolument from the union, either by way of salary or pension, can take his seat at the board of guardians, but there is no precedent or decision of the Irish Local Government Board existing which might rule the question. The English Local Government Board has been recently questioned on the subject, and has replied as follows:—"An appointment as medical officer under their regulations would not legally prevent the person so appointed from being placed on the Commission of the Peace or acting as a Justice. The board may, however, observe that the Statue 5 and 6 Vic., cap. 57, s. 14, would prevent his serving as a guardian so long as he holds the office of medical officer, as they consider that that enactment applies to *ex-officio* as well as to elected guardians."—Ed. M. P. & C.]

BALLINASLOE BOARD OF GUARDIANS.

Mr. P. Nonne, Secretary, Ahascragh Dispensary Committee, wrote saying that it was owing to Dr. O'Kelly's inability to procure a local professional man who would reside in Ahascragh that he was obliged to recommend Dr. Swanson; and the duties of medical officer could be more efficiently discharged by a gentlemen residing in Ahascragh than in Ballinasloe or Mountbellew.

The board ratified the action of the Ahascragh committee, allowing Dr. Swanson two guineas per week, when Mr. Ward proposed the following motion, which passed:—

Resolved—That for the future whenever a medical officer of this union applies for leave of absence for a limited period, in order to recruit his health, that such application be supported by the certificate of another medical man in the employment of this union.

ABBEYLEIX UNION.

Can a consultant be paid out of the rates in a private case?

A letter was read from Dr. Stoney, Abbeyleix, requesting the board for payment of four guineas, his fee for asisting at the amputation of Anne Lalor's arm, who was seriously assaulted some time ago, from the effects of which she died.

The result of those injuries was that it was found necessary to amputate her arm. Dr. Walsh was attending her, not on a red ticket, but as a paying patient. The woman's husband had some thirty acres of land at a moderate rate, and could not possibly be regarded as a pauper in any sense. Dr. Walsh made an application to the relieving officer for the assistance of another doctor in the operation, saying that the woman was unable to pay a second doctor, and that it was necessary to have one. The relieving officer, doing his duty, had Dr. Stoney sent. Now he (Mr. Comerford) regarded it as unfair to the ratepayers that they should be asked to pay the fee of this second doctor, considering that Dr. Walsh was being paid by this woman, and also her circumstances of life. It was true she might be in temporary difficulties, but it did not follow from that that she was to be regarded in the light of a pauper, and that the ratepayers should be asked to pay for the medical attendance.

The Chairman said he would regard it as illegal.

The Clerk read the law bearing on the question, but it was found not to apply specifically enough to this particular case.

Mr. Corcoran—We went so far the last day—assuming she was a pauper, we did not know anything of the circumstances—as to give two guineas. However, it was finally adjourned till to-day.

Mr. Comerford—If this were allowed it would be open to any of us, if we required medical attendance, supposing there was a necessity for a second doctor, to say, "We cannot afford to pay for a second doctor; we haven't the means," and it would then follow that the medical officer could make an application co a relieving officer for an assistant doctor, who would have to be paid out of the rates.

The Chairman—It is a thing this board should never allow. I notice that if you give a red ticket to a person occupying a certain valuation——

Mr. Comerford—Oh! then he should have to pay the doctor. But here the woman got no red ticket, and she was attended by Dr. Walsh as a paying patient.

Mr. Fleming asserted that the woman had no land, and that she was a pauper.

Mr. Comerford denied this, saying there was neither a deed of assignment nor bill of sale on the property.

The Chairman—Was she entitled to get a red ticket?

Mr. Comerford—Certainly not. Had I been asked for one as guardian of the district, I would have refused. No one holding over a rood of ground is entitled to a red ticket.

The Clerk—I beg your pardon—That is four out-door relief. A person may be destitute, while having thirty or forty acres of ground, and she would be entitled to it.

The Chairman—I think the law contemplates that you should be more liberal with medical relief than ordinary out-door relief. But is there no limit to free medical attendance?

The Clerk—Medical relief is given where the parties are destitute. If the parties were not destitute, and the doctor had attended them, it would come before the dispensary committee, and the doctor could take an action against the parties.

Resolution passed that payment be not made, pending the opinion of the Local Government Board on the point.

DROGHEDA UNION.

SUPERANNUATION.

The following was read :—

Local Government Board,
Dublin, 28th August, 1880.

Return relating to the superannuation of medical officers.

SIR,—The Local Government Board for Ireland transmit to you herewith a copy of an order of the House of Commons, dated the 16th inst., for a return relating to applications made by medical officers of workhouses and dispensaries in Ireland for superannuation allowances since the passing of the Medical Officers' Superannuation Act, 32 and 33 Vic., cap. 50 (2nd August, 1869), and the board request that, in order to enable them to make the required return, you will furnish them with the necessary particulars, forms for which are enclosed.

Three forms are enclosed, and the board will feel obliged by your making the return in duplicate.

By order of the board,
B. BANKS, Secretary.

[COPY.]

House of Commons,
Monday, 16th August, 1880.

ORDERED,—That there be laid before this house a return of the names of the medical officers of workhouses and dispensaries in Ireland who, since the passing of the Medical Officers Superannuation Act, 32 and 33 Vic., cap. 50, have resigned their offices and applied to their boards of guardians for superannuation allowances under that Act, with the causes for such resignation ; the ages and length of service as Poor-law medical officers of each person at date of resignation ; the result of such application to the guardians ; and the reason, if any, given by the said guardians for refusing the application.

ENNISKILLEN UNION.

DISINFECTING CHAMBER.

LETTER read from the Methodist minister, inquiring how the infected clothing and articles in the manse would be conveyed for disinfection to the disinfecting chamber.

Mr. Walmsley—I moved that none of the clothes be disinfected unless the urban sanitary authority pays some of the expenses.

Mr. Coalter—Do they pay for disinfection elsewhere?

Mr. Walmsley—They do.

Dr. Walsh—The urban sanitary authority paid a portion of the expense, and they should not pay twice.

Mr. Walmsley—I beg your pardon. They should pay a fair proportion.

Mr. Coalter—Has not every portion of the union the opportunity of getting the use of the chamber?

Dr. Walsh—It was the rural board paid for it. I make no objection if you charge fairly.

Mr. Lindsay—The disinfecting house was put up by the union, and I propose it be open to the union at large for the disinfection of clothes.

Mr. Jordan—I would move that the clothes be disinfected, and make a charge, but refund it if necessary.

MONASTERBOICE DISPENSARY.

NOTE read from Monasterboice Dispensary Committee saying that Dr. Murtagh was appointed at £3 3s. per week to do duty for Dr. Segrave during his illness.

Mr. M'Kenna—They gave him enough.

Mr. Markey—I thought that the committee had nothing to do with payment of the doctor or of his substitute ; they have nothing to do with fixing salaries or payments ; they can make an appointment ; that's all ; they outstep their authority when they do more than that.

Dr. Burke—The committee have nothing whatever to do with fixing the remuneration.

Mr. Markey—They have no right to fix a salary; that belongs to us ; we don't require any committee to do our business. They had no right to name a salary at all; £2 2s. a week is the sum ; I move that.

The motion was carried.

RICHHILL DISPENSARY.

LAST WEEK the committee of this dispensary met for the purpose of electing a medical officer. There were several candidates, but the election lay between Dr. Young, of Keady, and Dr. Fergus, of Kilkeel. The former gentleman was appointed on the chairman's casting vote.

SUPERANNUATION.

REFUSAL OF THE LOCAL GOVERNMENT BOARD TO SANCTION THE INCLUDING OF PUBLIC SALARIES IN ASSESSMENT.

A LETTER was received last week by the North Dublin Guardians from the Local Government Board acknowledging the receipt of the minutes of the board of guardians containing an entry of motion to the effect that a superannuation allowance be granted to Dr. Fausset, amounting to two-thirds of his salary and emoluments, as medical officer of the Clontarf and Howth (No. 1) Dispensary District, and also of his salary as medical officer of health of the district, and in reference thereto the Local Government Board desired to state that they had been advised by counsel that "the additional salary paid to a union officer, under the 11th section of Public Health Act of 1878, cannot be taken into account on calculating his superannuation allowance? and further that the fees paid to a medical officer for examining and certifying in the case of dangerous lunatics cannot be included in the document on which the superannuation is calculated. It will therefore be necessary to exclude from the calculation of the allowances proposed to be granted to Dr. Fausset the salary paid to him as medical officer of health, and to omit from the estimate of his dispensary medical officer any fees paid to him by the guardians under justices' orders in respect of alleged dangerous lunatics.

TO READERS.

THE Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. JACOB, at the Dublin office of this paper.

accepted their present appointments—to accept which many of them resigned appointments of greater pecuniary value. Justice must be done to St. Andrews. Its representative in Parliament can make his voice heard in Government circles, and the Scotch members generally will be grossly negligent as to their national obligations if they do not take up this question and insist on its being dealt with by the Treasury in no parsimonious spirit.

The medical profession, both because of its general interest in all scientific institutions and its special connection with St. Andrews, will cordially support any movement that may be set on foot to obtain justice to that University. A large number of highly respected members of the profession in London and the provinces hold St. Andrews degrees. A powerful association, composed of St. Andrews graduates, three-fourths of whom are medical men, exists under the presidency of Dr. B. W. Richardson, ascessor in the University Court, and a general impression prevails that St. Andrews may yet play a more important part than she has recently done, in conferring degrees upon able and experienced members of the profession who may be desirous of obtaining such a distinction, after a searching examination, but who may be unable to go into residence at a university or to renew their preliminary education. But whatever the future of St. Andrews may be, it is clear that she should not be permitted to perish of inanition, and we trust, therefore, that the Government will provide for her adequate maintenance.

THE CORK FEVER HOSPITAL CASE.

There are no circumstances under which a medical man can more reasonably claim the sympathy and sustainment of his professional brethren than when he, in the honest and competent discharge of his duty to his patient, becomes the victim of crazy, ignorant, and prejudiced people. To be made personally responsible for a fatality which he has devoted his most earnest efforts and his best skill to avert, is one of the many risks which every physician runs at one time or other of his professional life, but when the unjust accusations to which he is thus subjected develope from mere ebullitions of ignorance and prejudice into a malicious attempt to destroy the professional repute of the victim, then indeed, as we have said, he is entitled to every aid and countenance which his brother physicians can give him towards the vindication of his professional character and his personal honour.

Of such an attack, justified by not even the shadow of cause, and pursued with cruel vindictiveness and malicious persistence, Dr. MacNaughton Jones, of Cork, has been made the subject, and it will be for our readers, having been informed of the circumstances, to form an opinion as to the truth and justice of the charges made against him.

It appears that as far back as seven months ago, the household of a Mr. Crawford, a schoolmaster in the city, was afflicted with an epidemic of scarlatina of the most malignant type. Two of the children fell ill and were attended by Dr. Jones in consultation with Dr. Johnston. The cases proved to be instances of suppressed scarlatina, and though both children died, it was confessed by Mr. Crawford in his evidence that Dr. Jones had shown "every sympathy, care, and kindness possible," and neither then nor afterwards was there any suggestion whatever of any want of confidence by Mr. Crawford in Dr. Jones. After some time the third child fell ill with all the symptoms which the preceding fatal cases had shown, and, by the advice of Dr. Johnston, Mr. Crawford decided to place the child in the pay wards of the Cork Fever Hospital, to which institution Dr. Beamish, Dr. Budds, and Dr. Jones are physicians, and Dr. Adderly, resident medical officer.

It is alleged by Mr. Crawford that, in placing the child in the Hospital he had stipulated that it should not be placed under Dr. Jones's care, having heard, as he says, that that gentleman was "an enthusiast in experiments." Mr. Crawford sustains his statement that this bargain was made by the evidence of his wife, and by proof that he had asked Dr. Johnston for a letter to Dr. Budds, but that evidence goes to show no more than that Mr. Crawford expressed a wish on the subject, while it is clearly controverted by the testimony of Dr. Adderly that Mr. Crawford had expressed a desire to place the case under Dr. Jones, that the register had been shown to him with the blank for the next admission opposite Dr. Jones's name, and that neither then nor afterwards did Mr. Crawford offer any objection, but approved of the child being put in charge of Dr. Jones, and placed in Dr. Budds' ward in order that he might be near his aunt, who was also a patient. The child was brought to hospital on Sunday evening, presenting no obviously serious symptoms; the usual nursing directions were given, and the night was passed without any notable circumstance, save the occurrence of occasional slight delirium. At 10 a.m., on Monday morning, Dr. Jones came to pay his usual hospital visit, and was shown the child. At once, as sworn by Dr. Adderly, he sounded the alarm, expressed his great apprehension of a fatal issue, and ordered chicken-broth, a hypodermic injection of hydrochlorate of pilocarpine every three hours, a "pack" (meaning, as he says, a wet pack), and chicken-broth. An hour afterwards the father called and saw the child, knew that he was under Dr. Jones's care, heard of the physician's unfavourable prognosis, and was told of the intended hypodermic injection, and it does not appear by word or act he expressed himself as dissatisfied in any way with the treatment past or proposed.

Being naturally anxious to have the verdict from Dr. Jones's lips, he went at 1 p.m. to that gentleman's house, where, after some conversation as to the state of the child, he propounded the peculiar suggestion that Dr. Townsend, a physician entirely unconnected with the hospital, should be brought to see the child as a consultant. To this Dr. Jones—as might have been expected—gave a decided negative, but added that, if Mr. Crawford pleased, he would willnigly transfer the case to either of his colleagues, Dr. Budds or Dr. Beamish. This offer Mr. Crawford did not accept, though he now swears that he distrusted Dr. Jones from the first—bargained that the child should not be under his care, and disapproved altogether of his proposed treatment—and he went away without giving Dr. Jones—as he admits—the slightest reason to suppose that he objected to anything proposed to be done. Meanwhile

Dr. Adderly had not carried out Dr. Jones's orders, he explaining that the chicken broth had not been given because there were no chickens in the hospital. The pilocarpine injections were not given because he omitted to do as he was ordered, and sent to the wrong place for the drug. The "pack" was not used because he thought a dry pack was meant, his idea of a pack being to roll the child in blankets. It was late in the afternoon when the messenger came to Dr. Jones's ophthalmic hospital for the pilcoarpine, and Dr. Jones then directed that the injection should not be given until he could give it himself at his afternoon visit to the hospital. At five o'clock he arrived, saw the child, expressed himself as altogether without hope of his recovery, and as a *dernier ressort*, gave the hypodermic injection, and went away, saying that he could do no more. Shortly afterwards the child became delirious, showed symptoms of chest effusion, and in five hours died.

This is the "round, unvarnished tale" which we have eliminated from the ten-column newspaper report before us, and having, we believe, omitted no point which could bear upon the charges against Dr. Jones. Some time after the death of the child Mr. Crawford preferred charges against the Hospital administration and against Dr. Jones, before the Board of Governors of the Hospital, who, after an investigation, declared themselves satisfied that the accusations were not sustained. But this did not satisfy Mr. Crawford. Selecting the tribunal which would cost least money and would injure Dr. Jones's reputation most seriously, he employed a solicitor to raise the question before the Corporation by way of an objection to the usual grant made annually for the maintenance of the Hospital. There, before the chief citizens of Cork, where every word spoken was noted by the reporters, where Dr. Jones's presence or defence was impossible, Mr. Crawford elected to follow up his onslaught, and he did so by a tissue of statements which could not be then contradicted, and many of which have since proved entirely without foundation. It is within our knowledge the first occasion, and we trust it will be the last, that a solicitor has been permitted to make a civic council the arena of a spiteful personal attack, and to enter upon a public criticism of an abstruse medico-physiological problem, with all the variations upon truth which the legal imagination usually suggests, and we feel bound to say that the City Fathers of Cork displayed little sense of their proper functions, of the dignity of their assembly, or of fairness and justice, when they allowed their council chamber to be used for the gratification of personal malice. Be that as it may, the case on behalf of Mr. Crawford was put forward in its entirety, and, being entirely uncontradicted, it was decided that the subject be referred back to the Board of Governors for a further inquiry. All the essential testimony at that inquiry is now before us, though a further meeting has yet to take place and a decision to be finally come to; and with after perusal of the full testimony we feel justified in saying, with all emphasis, that no matter what view outsiders may hold, the medical profession fully and honourably acquits Dr. Jones of either want of care, lack of skill and capacity, or rashness of judgment, and we believe we speak the almost unanimous feeling of his brother physicians throughout the kingdom when we say that no fact is disclosed in the evidence which reflects either upon his professional character or his private worth, and that he has done nothing which each and every hospital physician may not be called upon to do to-morrow under similar circumstances. He is accused of having refused to admit a private physician to the case of a patient in his hospital, there being already two other physicians attached to the institution. The accusation is proved, and we say that the course pursued by him was not only justifiable, but proper and expedient. No one has ever heard of an extraneous physician being asked his opinion as to a patient in a public institution, except simply as a visitor and on sufferance, and we believe that no hospital could be worked with benefit, which admitted the principle that the patient's relatives should fetch in their pet outsider as a consultant.

As to the propriety of Dr. Jones's administration of a hypodermic injection of pilocarpine, we decline te enter into controversy with Mr. Crawford or his solicitor, or with either the Cork Town Council or the lay Governors of the Hospital.

To Mr. Crawford's ideas on the point little regard need be given, considering that his blank ignorance of the subject is marked by his mistaking a hypodermic injection for an injection into the veins. In justification of Dr. Jones before his own profession—who alone have jurisdiction upon such a matter—we may remind our readers that diaphoresis is, in a case of suppressed scarlatina, often the arbiter of life or death; and that, to obtain it, any or every resource must be adopted. Every therapeutist now knows how that pilocarpine—the alkaloid of jaborandi—is the most potent agent for causing a speedy perspiration; that it has been and is daily being employed by some of the highest authorities in the world at home and abroad for this purpose; and that its use is now no more an "experiment" than the use of atrophine or methylene. If Dr. Jones had shrunk from the responsibility of using this or any other remedy of equal repute in such a case as that of this poor child—even supposing that the use was difficult and dangerous—he would be answerable to his conscience and his superiors in the Hospital for shortcomings in his duty. If even it were true that the drug hastened death—which supposition is not sustained by a spark of evidence in this case—the physician who used it conscientiously and to the best of his skill and learning would still be altogether free from blame.

There is one aspect of this case to which we hesitate to refer, or to regard as suggesting a possible solution of the virulence of this attack on Dr. Jones; but we may mention a fact upon which each reader will put his own construction—a Professorship of Surgery in the Queen's College, Cork, will be appointed in a week or two—Dr. Jones is a promising competitor. There are other competitors of different religion and politics. Can it be that this cruel and unmerited attack upon his professional character is the offspring of the coming election?

APPARITIONS.

THERE is something far from satisfactory in the continued recurrence of the impostures termed by over-credulous believers in the marvellous, "apparitions." Within the last few years the number of these clumsy frauds has

largely increased, and, at the present moment, masses of illiterate persons are being daily moved to wondering awe by a miracle epidemic in two obscure Irish villages. These exhibitions would be undeserving of serious notice, were it not for the effects they are possible of producing. It is, unfortunately, too true that the uneducated mind is always willing to snatch at any objective experience, around which the shroud of mystery is cast, and forthwith endow it with the attributes of the wonderful, simply because it chances to be incomprehensible to the narrow intellectual capacity of the herd that gives it credence. Much, too, of the miracle-mongering of the day depends for its undoubted success on its being associated with a religious fervour, before which the proper functions of the reason are in abeyance. Appeal is made directly to the susceptible imaginations of a class that is willing to be led by any semblance of authority; and use is made of the traditional powers of the church to foster a desire for absolute control over the consciences of its subjects. We do not attack the advocates of miracles in any way adverse to their legitimate assumptions; but the influence they exert is, from the point of view we occupy, one of irremediable evil. The consequences that follow from the repetition of scenes in which prominence is given to the rehabilitation of long dead persons, the possession of life-like attributes to inanimate objects, and the exercise of healing virtues ascribed to impossible sources, are such as demand the earnest attention of everyone who will accept the truth, *Salus populi suprema lex*. That very many persons are affected for life with a ruling belief in supernatural occurrences, through the bearing of so-called miracles worked before them, is in the knowledge of every physician whose speciality lies amid mental diseases; and all of these can recount instances of incurable monomania initiated by some such performance as is taking place at Knock at the present time. Controversy on the importance to be attached to accounts of the miracles quoted from an earlier age, there must always be, so long as natural knowledge is confined to a section of the educated classes. Until the mind has been trained to a correct appreciation of the inviolable connection between cause and effect, and the relation of all phenomena to antecedent producing agencies, there can be no common concurrence of opinion on the significance of the signs and wonders with which localised religious communities are occasionally deluged.

The condition of the mind willing to place unquestioning faith in the reports brought to it of the marvels of miracledom is very much akin to that referred to in our last at Glasgow, in which the outrageous quackery of a bespangled woman is accepted as a realisation of the highest medical skill: until the pretensions of the one receive their fitting reward at the hands of the public, the other will continue to exert unchecked sway. In view, however, of the lamentably evil effects thus produced, it becomes a duty for the medical profession to do something that shall avail, if possible, to limit the mischief that follows from the practices it condemns. It recognises how great the mischief is, and it can unhesitatingly define the limits within which its destructive power is evinced. The religious monomaniac, the hysterical invalid, the victim of hallucinations, the moping hypochondriac, all these ranks of the afflicted are amply recruited by those who have yielded unquestioning obedience to the impulse that guided them to place their trust in sensations excited by occurrences for which they could assign no earthly explanation. It is not to be overlooked, moreover, that it is first among the ill-fed, ill-conditioned, and scarce educated people, that we find the earliest exhibitions of a credulous spirit; a class from which there are always many ready to accept an ill-defined call to the performance of unusual offices, in proof of a claim to supernatural prerogatives. Hence the innumerable instances of fasting among the lower orders; of being possessed by spirits good and evil, and of other special proofs of an assumed superhumanity. Asylums, both public and private, abound in this description of patients, and it is perhaps to be wondered at that the higher classes of society are so little affected as they are by the influence of the more uneducated enthusiasts. In some degree they are so, however, but the one encouraging feature to be observed is, that the greater the degree of mental culture, the less is the effect produced by the exhibitions that so readily impose on the ignorant rustic. Education is the engine, by aid of which we shall eventually be cleared of one of the pests of the modern social system; before it the whole array of supernaturalism will fade away, and with it the distressing symptoms of a great mental affliction will disappear from our midst. Meantime, there is much to be done to counteract the prevailing spirit; this is a task that falls to the physician's lot, and it becomes him to look the matter in the face, and to recognise it as one having to do with his province. He cannot enlighten the ignorance that affords a home for the "apparition" malady, but he can, in a measure, reduce the extent to which it works physical destruction, by judicious employment of the remedies familiar to him, as being efficacious in states of mental disturbance. It is futile to trust that the exposure to which many of the "miracles" have had to submit will turn the peasant from his faith, while he is always ready to be imposed upon afresh. The history of Spiritualism has shown this again and again, and the development of a distinct phase of insanity due to the religious and spiritualistic revivals helps us to appreciate at its real importance the evil at work in our midst. It opens almost a new field of medicine, and in the immediate future it will demand the serious consideration of those on whom its repression will be chiefly dependent.

Notes on Current Topics.

Station Hospitals in India.

INFORMATION has reached us that the introduction of station hospitals has been sanctioned at certain places occupied by troops in India. Having in view the interests of the troops themselves, and of the military service generally, we regret this exceedingly, believing as we do that the measure is a retrograde step, and, in fact, a recurrence to conditions which had to be done away with in that country so long ago as the latter end of last century. This fact, indeed, is patent enough to those who read the history of army hospitals; but it is to be feared that, like many other so-called "reformers," the number of those now so called who refer to the past as a

preliminary to enunciating their "discoveries," is comparatively small.

This scheme of station hospitals in India has, we believe, been strongly opposed by officers high in rank and of much experience in wars in that country. There are a good many of those who took part in the campaign of the mutiny who recollect the facility with which regimental and "general" establishments on that occasion worked together and interchangeably; they testify to the perfect adaptability of the regimental system to times of peace, and to the requirements of every class of persons in a regiment, including patients and medical officers. Nor do some of the statements we have seen indicate any single respect in which, during the present war in Afghanistan, "unification" has shown sufficiently over that whose place it took, although several very serious objections against it might readily be construed out of certain occurrences that have been mentioned in connection with that war.

So far as the destruction of the regimental system on home service is concerned, there are those who consider the results the very reverse of encouraging. These naturally look with apprehension to the re-introduction into India of the *system* already condemned in that country. Among many other disadvantages attending it one is expense; this item must become considerably larger than under the regimental system, as regards establishment and equipment; the necessity in our larger stations of carrying patients long distances to the *general* hospitals, while suffering from cholera, ardent fever, heat apoplexy, and so on, must necessarily be extremely objectionable; and in so far as the necessities of families are concerned, whether of officers or soldiers, the objections against having to be attended by a succession of new and strange medical officers can only be fully appreciated by those whose misfortune it is to have been placed in such circumstances.

Milk Diet in Heart Disease.

M. Potain, at the recent meeting of the French Association for the Advancement of Science, read a paper on this subject. Milk diet is particularly efficacious in secondary cardiac affections, as hypertrophy or simple dilatation of a gastric or renal origin. The diet modifies the condition of the kidney and the stomach, because it gives these organs almost complete rest; therefore to be thoroughly efficacious it should be absolute and more or less prolonged. It may be usefully employed in cases of simple reflex palpitation, of gastric origin. It may also be advantageously used for its diuretic action in dropsy, especially, and perhaps exclusively, when the dropsy is of renal origin.

Private Retreats for the Insane.

In connection with the Reports of our Special Commissioner on private asylums, in progress of publication, a correspondent draws attention to the marked change that has within recent time taken place in the popular estimation of these institutions. When a review of the latest expressions of opinion concerning them is made, it certainly is astonishing to find how the old ignorant abuse is gradually giving place to a correct and rational appreciation of the great benefits derived from the private asylums for the home treatment of insanity. It should be fully admitted that this is chiefly due, however, to the outspoken convictions of those whose position and authority enable them to judge by the results they are constantly witnessing. The Commissioners in Lunacy in their visit and in their reports testify in the warmest manner to the great excellence of the work accomplished in the asylums visited by them, and under the control of private licenses. The emphatic utterances of men like the Earl of Shaftesbury, and who are heart and soul in a desire to do the utmost for the mentally weak; men, too, who have the fullest confidence of the public, have done, and will do, an immeasurable amount of good in allaying the unfounded fears aroused by the inconsiderate and intemperate articles of the sensationalists. After six months labour, carefully sifting all the evidence procurable, a Parliamentary Committee could not discover, as Lord Shaftesbury declares, a single instance of improper committal. It may be hoped that the prejudice which *has* existed will no longer obtain, and that a more familiar and juster appreciation of private asylums will take the place of the older intolerant objections to them.

Snake-bite.

Land and Water recounts a story of recovery from the bite of *Crotalus horridus* on the part of Dr. Arthur Stradling, which possesses some interesting features. The animal was a small one, under eighteen inches long, and bit Dr. Stradling on the wrist, one fang remaining in the flesh. This he removed, and for some time felt no ill-effects. Four hours subsequently, however, the lymphatics of the arm above the punctures were swollen and painful, this being followed by dizziness and a burning sensation over the body, but the temperature was no more than 96·4°. Dr. Stradling applied nitric acid to the wound, and forthwith became insensible. Dr. Wyman saw him at 11 a.m., six hours after, when his face and lips were pale, expression dull; eyes fixed and glassy, the lids remaining open or shut, as they were placed, pupils contracted; general surface of body warm and moist, but feet and legs cold to above the knee. Temperature in axilla 99·8°; respiration 13, shallow. The intercostal muscles were paralysed, the breathing being mainly abdominal, irregular, and occasionally stertorous. The lower extremities were completely paralysed. Dr. Wyman sucked the wounds on the wrist (one of which was blackened), applied nitric acid to them, and ligatured the arm above the elbow tightly. Internally he administered æth. sulph. ʒi. twice in about twenty minutes, and then half a drachm with the same quantity of compound spirit of ammonia every twenty or thirty minutes till three in the afternoon, when, for the first time, there were signs of movement, in the shape of a well-defined backward arching of the patient's body; hiccough took place sometimes, and twitchings of the muscles of the upper part of the chest and shoulders. There was no vomiting, but a painful feeling at the heart was complained of, and a temporary delirium exhibited. Beef-tea, and egg and brandy, alternately with ether and ammonia, were administered, and gradually recovery took place, the power returning in order to the right arm, right leg, left leg, and left arm. Consciousness was com-

plete at five o'clock, but was accompanied with return of weakness, and slight hysteria succeeded. The patient records that he awoke free from pain "but weak as a baby, and became a mere lay figure for the exhibition of chicken broth, jelly, smelling salts, strong drinks, misplaced sympathy, arrowroot, and slippers."

Questionable Physiology.

THE body of the convict Menesclou, who was executed last week in Paris for the murder of a girl, was according to *Le Figaro*, submitted by Dr. Sappey to an experiment of which it is difficult to see the exact bearing. Some blood, freshly drawn from the carotid of a dog, was injected subcutaneously in the scalp of the corpse, with the result that the colour of the cheeks was restored, while there was a perceptible movement of the lips, and twitchings of the facial muscles. No other part of the body, however, responded. The details of the experiments, as quoted by *Figaro*, are meagre in the extreme, but in any case the result does not bear much promise of any advantage to science, and might well have been left untried.

Cholera in India.

THE cholera epidemic in India is to all appearance a severe one; and the following telegrams, which appeared in the *Bombay Gazette*, illustrate the extent of its ravages up to the dates given :—

"Simla, August 18.—A cholera epidemic broke out at Tangi on the 11th, and up to yesterday morning forty cases were registered, of which twenty proved fatal. Dr. Taylor, who had just returned to Peshawur from Tangi, heard a report of the epidemic having reached Charsadda, but there is no such report from the police. Dr. Taylor thinks that if the traffic on the Cabul River is stopped its spread to this side might be delayed until our army goes through. Orders to stop the traffic have accordingly been issued. The local authorities recommend that our army should be hurried through, and advise the Kohat route. The engineering party making ferry arrangements at Attock are heavily crippled by the cholera.

"August 19.—Surgeon-Major H. W. Bellew, C.S.I., Sanitary Commissioner of the Punjaub, proceeds immediately to Peshawur to ascertain the state of the outbreak of cholera at Tangi, and to advise the Government regarding the danger to be apprehended from the influx of troops shortly to take place. As cholera at Tangi broke out on the 11th, and as a quarantine is discouraged by the Government of India, there can be no object in stopping traffic, and the Peshawur Commissioner's original order to that effect is accordingly cancelled."

Hints to Hospital Visitors.

The "Sunday at Home" magazine in an article on the subject of hospital visiting, gives certain hints which, if acted on by all who devote a portion of their time to this good work, would react with great advantage to the patients in these institutions. Especially should the suggestion be adopted, to gain the confidence of the invalid by avoiding all pretence to patronage or fussiness. The writer of the article advises all visitors, however short a time they mean to give to each patient, to sit down by their bedside, not on any account to speak to them standing up and leaning over their bed. This worries and fusses an invalid, and at once does away with the soothing effect which is so much to be sought after. Equally excellent, too, is the advice contained in the following extract. We commend it heartily to every charitably minded hospital visitor :—

"If posible, follow up the helpless cases in their own home, where, after leaving the hospital, they are generally in great want of some small comforts. The gift of a wicker-chair, a couple of cushions, flannel, old linen, or whatever is most needed, is very valuable in supplementing the good gained within the hospital walls. The wants of most inmates of our hospitals are so very real and so very great that they are not met by the casual gifts of flowers and tracts only, and though it is natural to wish to please a great many sufferers by kind words vaguely distributed, far more real good would be done by narrowing the circle and thoroughly working two or three cases."

A Prescribing Clergyman.

AN inquest was held last month at Monkwearmouth, on the body of a woman, æt. 73, who was shown to have died from mortification resulting from hernia. The deceased had concealed the cause of her illness, and the vomiting, pains in the bowels and purging she suffered were supposed by her neighbours to be caused by bile. The Rev. Thomas Snell, a dissenting minister, was asked to see her. It was not usual, Mr. Snell said at the inquest, for him to have medicine in his pocket, but he happened to have some homœopathic trituration of ipecacuanha which he gave her; he thought she was suffering from bile. He did not know what she died of, but heard yesterday she was suffering from hernia, but she had not even disclosed this to the neighbours. Dr. Blumer stated that he found femoral hernia on the left side, which he reduced. Mortification set in, and caused death. If any qualified medical man had been called in on Thursday or Friday, the hernia could have been reduced, mortification prevented, and life saved. The Coroner considered that they could not attach any criminal consequences to Mr. Snell's conduct, as it was an error of judgment. A person going out of pure kindness, and prescribing something—and it was not suggested that it did any harm—must not be found fault with because he did not possess sufficient skill or knowledge to perform an operation. The jury came to the conclusion—as some of their members cited similar cases where persons at earlier periods of life and stronger than deceased, in which the highest medical authorities in the North of England had been called in, had succumbed to hernia—that in this case there was no blame attached to anyone, and that deceased had died from natural causes, namely, mortification arising from hernia.

If the person who is responsible for the death of this woman had been a druggist or a bonesetter, instead of a dissenting parson, he would probably have been sent for trial for manslaughter, and the coroner would not have thought it necessary to plead his cause as he did. Without doubt, the woman lost her life because this meddlesome parson undertook her treatment, without either the skill to do so, or the care to make a sufficient examination of her symptoms, and he may thank the judge and jury for having "cooked" the inquiry, and saved him from jail.

The Pathological Relations of the Eye and Ear.

At the recent meeting of the French Association for the Advancement of Science, Dr. Dransart read a paper entitled, "Clinical and Pathogenic considerations on the Pathological Relations between the Eye and the Ear" (*Le Progrès Médical*). He bases the work on four cases, which may be thus summarised: 1. A tinker lost the right eye in 1870 (wound from a fragment of iron, traumatic cataract); as the result of this accident he became deaf of the right ear. In 1880 he received a similar fragment in the left eye; he became deaf of the left ear. He was an alcoholic subject. 2. A child, æt. 12, received a snowball in the right eye; he became deaf of the right ear. Father and mother syphilitic. 3. A girl, æt. 18; scrofulous, deaf, and almost blind. Multiple lesions of the cornea, sclerotic, and iris. Double iridectomy; sight was restored to the patient, and the hearing improved. 4. A girl, æt. 8; deaf, ocular lesion, iridectomy, amelioration of vision, and diminution of deafness. After calling to mind the anatomical relations existing between the eye and the ear, through the medium of the trigeminal which supplies both (by the otic ganglion), the author considers the reflex effects of dentition and of certain wounds. He proposes, with reserve, the conclusion that there exist between the eye and the ear pathological relations of a reflex nature; these relations, which take place through the medium of the trigeminus, are such that a wound of the eye may induce deafness, or may ameliorate a deafness already existing. This action of the eye on the ear, which seems capable of producing what we call *reflex deafness*, or of ameliorating deafness already existing, seems to occur preferably under certain pathological conditions, such as syphilis, alcoholism, lymphatism, or scrofula.

Sad Deaths of two London Practitioners.

Bathing fatalities have been more frequent this season than usual, and among the latest victims may be mentioned Dr. Campbell, of London, who was drowned at Coatham, Redcar, on Thursday last while bathing. Several other persons were bathing at the time, among them being two youths namod Robson, of Durham. Dr. Campbell had left the water and returned to his bathing-machine, when he was requested by the elder Robson to assist his brother Charles, who had been caught in a current, and was then struggling in the water. Deceased at once took out a life-buoy to Robson, and then swam towards the shore. When he had gone about twenty yards he called out to Robson to help him; but Robson, owing to the strong current, was unable to reach him. A boat which had put off had by this time reached the spot, and Robson was taken on board. The occupants of the boat next proceeded in the direction of the deceased, but before they could reach him he was observed to throw up his hands, and immediately disappeared. Dr. Campbell was an excellent swimmer, and he must have been seized with cramp.

The second death is, perhaps, even more melancholy. It is that of Mr. Edward Amphlett, F.R.C.S., Assistant Surgeon to, and Demonstrator of Surgical Pathology at, Charing Cross Hospital. On Thursday morning last, shortly before nine, he was found holding on to the bannisters of the stairs, unable to proceed to his room, and Dr. Murrell, residing next door, Dr. Fox, and other physicians were immediately called in. Death took place two hours after. Surrounded as it was by suspicious circumstances, a coroner's inquest was held on Saturday, when Dr. Murrell deposed that when he saw deceased he was sensible, but the pupils of his eyes were contracted. On charging deceased with having taken something in the way of chloral or morphia, he denied it. On being taken into a room, deceased became very drowsy, and the usual steps were taken to restore animation, including the application of galvanism, but all was in vain. He made a post-mortem examination, and came to the conclusion that the death was from some overdose of medicine, probably morphia, or possibly morphia and chloral. The coroner asked if there were any letters that would throw light as to the state of mind of the deceased at the time? A brother of deceased replied that there were some letters, and it appeared that there had been also a disappointment in love. Several letters were here put in, and one from a lady to whom deceased had been engaged was read, in which she referred to giving him up in favour of another gentleman. A copy of a letter from the deceased to the lady was also read, in which he stated that he had received his death-blow. The coroner having summed up, left the jury to say whether the deceased had died by his own hand, or been accidentally poisoned; and after a stormy discussion, lasting half-an-hour, the following verdict was returned: "The jury find that the deceased died from an overdose of narcotic poison, taken unconsciously whilst suffering from excitement; and, further, that such death was the result of misadventure."

The International Medical Congress.

The arrangements for the meeting of the Congress in London next year, so far as they have been determined on, are as follows:—The Congress will be carried on in fifteen sections. The days of the meeting will extend from Wednesday, the 3rd, to Tuesday, the 9th of August, both days included. An evening reception will take place on Tuesday, the 2nd of August, on which day admission tickets to the Congress may be procured at the office of the Reception Committee.

The meetings will be chiefly held in the halls of the University of London, and in Burlington House, where in a most liberal manner the use of rooms has been granted to the Congress by the authorities.

Besides the general and sectional meetings there will be a museum to which contributions of professional interest will be made. Evening receptions will be held, and excursions arranged to various places of interest.

Ladies will be invited to the social and ceremonial meetings of the Congress, but will not be admitted to its business meetings. The expenses to be incurred must necessarily be very considerable, and the Committee appeal to the whole profession of the United Kingdom to subscribe funds sufficient to relieve them from all difficulty in making suitable arrangements. A payment of one guinea will be required from intending members at the time of taking out their cards of admission. This will constitute membership, will admit to all the meet-

ings, and will entitle each member to a copy of the "Transactions" of the Congress; this sum, however, will barely cover the cost of publishing the "Transactions," and will be quite distinct from the subscription now asked for.

The Origin of the Stethoscope.

M. CHEREAU, in a French medical journal, gives the following interesting history:—

One day, as Laënnec was crossing the court of the Louvre, he observed some children who, with ears applied to the two extremities of a long beam, were transmitting reciprocally the light sound provoked by the stroke of the finger against the opposite end. In the intermediate space no sound was perceptible. The careful observer reflected, and soon, like Archimedes, he was able to exclaim, "I have found it!"

Some time afterward, in fact it was in 1816, being consulted for a young woman who presented general symptoms of heart disease, in which percussion gave small results on account of the stoutness of the subject, the age and sex of the patient forbidding his listening directly with the ear, he remembered the children of the court of the Louvre. Immediately he took a paper copybook, of which he made a roll closely pressed together, placed one end of it upon the chest of the young woman, applied the other to his ear, and found with pleasure that in that manner he could perceive much more clearly the beats of the heart. So a play of children and regard for modesty were two facts which led to the discovery of medical auscultation.

Homœopathic Dosing.

A CORRESPONDENT of the *Chemist and Druggist* says: "Homœopathy is either a huge lie or a Divine truth," so its professors tell us, and I for one am willing to acknowledge it so; but which of the two may be explained by the following case:—

A lady suffering from neuralgia recently went to a celebrated "homœopathic" (?) physician in the West End. The following were the prescriptions given:—

(1.) Quin. sulph. solub., iv grs.
Fiat pulv.
To be taken four times a day.

(2.) Lin. belladon. (B.P.), ℥ss;
Chloroformi, ℥ss;
Nepenthe, ℥j.
M. Fiat linim.

(3.) Allen & Hanbury's "Perfected" cod liver oil, Lbss.

(4.) Quin. sulph., xlviii grs,;
Sp. chloroformi, ℥j;
Sp. vini rect., ℥j;
Ac. hydro. dil., q.s.;
Aq. ad, ℥iv.
A teaspoonful three times a day.

(5.) Liq. strych. nit. (1-200), ℥iiss;
Ac. nit. dil. (1-10), ℥iiss;
Aq. ad, ℥iv.
A teaspoonful three times a day in water.

The whole of these medicaments were to be used concurrently except Nos. 4 and 5, which were to be used alternate weeks.

I myself saw the prescription in question, so can vouch for the truth of this statement. Verily "homœopathy is a huge lie."

Health of the Troops in Afghanistan.

A CORRESPONDENT in the last number of the *Bombay Gazette* to hand, says the strain upon the medical officers, especially of the Cabul force is very great, and some idea of the work to be done can be realised from a paragraph in to-day's orders; two surgeons who reported their arrival *to-day* from Peshawur are ordered to return to India tomorrow with the native sick convoy. The 67th Foot and 45th Sikhs have furnished the heaviest percentage of sick, and the reason is not far to seek. These two regiments were sent to garrison Jugdulluck in the early days of June, and the trying march in the sun laid the seeds of fever in most of the men. Not an officer of the 67th, from the Colonel downwards, escaped a few days on the sick list, while the men have never fully recovered their old strength. The two Highland regiments, the 72nd and 82nd are exceptionally healthy, less than 50 sick being sent from their hospitals. The 9th Foot is still feeling the effect of its stay in Peshawur during the first campaign, and though out in camp their health has improved, they cannot altogether shake off the insidious Peshawur fever. Taken all round, however, the deaths from sickness among Europeans have been very few in number.

French Association for the Advancement of Science.

AT the recent meeting of this Association MM. Boutmy and Brouardel described the results of their experiments on the development of cadaveric alkaloids. During the progress of cadaveric decomposition they find that certain substances are formed possessing the general characters of alkaloids, and poisonous to man and animals. Medico-legally, the matter has important relations, as well as surgically in the case of, say gangrene of a limb.

M. Jollet contributed a series of graphic tracings representing the variations in the heart-beat in animals under the influence of different poisons (aconitine, digitalis, &c.). From his investigations it appears that each poison possesses a special and almost invariable tracing, a fact evidently very important, medico-legally. Thus, infinitesimal quantities of poison deposited in the liver, unrecognised by chemical procedures, could, by injecting them under the skin of a frog, be detected, and the nature of the substance determined by the tracing obtained, so sensitive is the physiological reaction. It was suggested that this method might perhaps distinguish alkaloids from the cadaveric alkaloidal bodies mentioned above.

At the same meeting MM. Wiel and Duval related some experiments on the abdominal course of ovules as directed towards the fallopian tube by vibratile cilia. Upon the peritoneum of female frogs they have always found at spawning season an epithelium with vibratile cilia in vigorous movement. They never observed these elements in the male frog, nor in the female, except when spawning. They have also noticed them in the female cat when rutting. In the human female M. de Sinéty met with vibratile cilia in abundance on tumours removed from the pelvis a few days before the menstrual period. From these data they derive the theory of the *intra-abdominal migration of ovules by vibratile cilia.*

Pilocarpine in Asthma.

Some person with more time on his hands than brains in his skull, and with less wit than good manners, has perpetrated a hoax on us which we should not think worth notice but out of regard to the gentleman whose name is used. The letter on "The Hypodermic Injection of Pilocarpine in Asthma," which appeared in our issue of the 1st of September, purporting to have been written by Dr. Carey, ex-Physician to Barrington's Hospital, Limerick, was not written by that gentleman. We need hardly say we do not know the author, which is to be regretted, because it is a pity that so illustrious a member of the profession should "blush unseen." However, as far as we are concerned, he is quite welcome to the internal gratification of his poor little joke, and we cannot but envy him the possession of a mind so constructed as to delight in this sort of exploit.

A Bogus Suicide.

In our issue for September 1st, we mentioned that the notorious bogus diploma-monger, Dr. Buchanan, of Philadelphia, who was out on bail, and would have been arraigned for trial on the 17th ult., had the previous night jumped from the ferry-boat on the Delaware river, and was supposed to have committed suicide; but as the body then had not been found the police thought he might have escaped. Fully aware of the character of their prisoner they were ceaseless in their watchings, and finding that he had arranged for a bogus suicide, tracked him to Michigan, where he was captured. The bogus suicide was cleverly managed, and as cleverly defeated by the police. After changing his clothes and altering as much as possible his outward appearance, he absconded to Canada, dodging about from place to place until his second arrest.

"The Lady Doctor" in Glasgow.

Madame Enault, the "lady" quack who figured to such profitable purpose in Glasgow lately, and whose doings we exposed in our last issue, has suddenly disappeared from the scene of her triumphs, as she has before now done in other places. It is believed that with half-a-dozen of her confederates she has taken the road for Carlisle. It is calculated that during her brief sojourn in Glasgow the woman drew over £4,000 from the sale of her nostrums. Great credit is due to the Glasgow press for, even at the eleventh hour, having so successfully exposed this gigantic fraud; and all sensible people will agree with the *Glasgow News* that there has been a gross miscarriage of justice somewhere.

Headache from Tincture of Iron.

A writer in the Boston *Med. and Surg. Journ.* says:—"During the administration of the tincture of the chloride of iron, functional derangements of the stomach and liver often arise, with furred tongue, impaired appetite, headache, &c. These symptoms rapidly disappear upon adding one-half grain of the chloride of ammonium to each minim of the tincture. This combination is useful in cases of heart disease accompanied by anæmia and debility.

Removal of Nævus.

Dr. Sigler states in the *Pharm. Centralb.* that nævus may be removed by means of croton oil in the following manner:—Push a number of needles through a cork, so that the points project 3 to 4 millimetres. Dip the points in croton oil, then insert them in the mole and withdraw. This is a sort of Baunscheidtismus. A scab will form upon the mole; and after it has dried up and dropped off, the operation is twice more repeated.

Preserving Rubber Instruments.

Various articles and instruments made of rubber are apt with time to become dry, to crack, grow brittle, and lose their elasticity. Dr. Pol recommends the following simple mixture:—Water of ammonia one part, water two parts—in which the articles should be immersed for a length of time varying from a few minutes to one-half or one hour, until they resume their former elasticity, smoothness, and softness.

Starvation Heroes.

After all it would seem that Dr. Tanner is only a plagiarist, and 400 years behind the time. In the church of St. Mary, at Bury St. Edmunds, is an altar tomb, surmounted by a recumbent figure of a starved man, the details of which are well executed. It was erected to the memory of John Baret, who died of starvation in 1463, while attempting to fast forty days and forty nights.

Dispensary Houses in Ireland.

Mr. Bellingham, M.P., has obtained from Government a return, showing how many Boards have availed themselves of Mr. Bruen's Dispensary Houses (Ireland) Act, 1879.

The death has been announced of Professor Buhl, the value of whose researches into the histology of tubercle especially has been universally recognised by pathologists.

The death rate from the seven principal zymotic diseases in the large towns last week ranged from 4·2 and 4·9 in Plymouth and Brighton, to 17·0 in Norwich, 17·4 in Salford, and 19·3 per 1,000 in Leicester. Scarlet fever showed fatal prevalence in Norwich, Dublin, and Sunderland. Diphtheria caused 2 deaths in Portsmouth, and 2 in Birmingham. The deaths from enteric fever were proportionally excessive in Portsmouth and Plymouth. The deaths referred to diarrhœa in the twenty-one towns, which had steadily increased in the eleven preceding weeks from 51 to 994, declined last week to 882, and were equal to an annual rate of 6·7 per 1,000. Small-pox caused only 5 deaths in London, one in Dublin, and none in the other towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Registrar-General's Returns.—According to the weekly returns of births, deaths, and marriages for the eight principal towns in Scotland, the death-rate for the week ending

with Saturday, the 4th inst., was 19·3 per 1,000 of estimated population. This rate is 3·2 above that for the corresponding week of last year, and 0·9 above that for the previous week of the present year. The lowest mortality was recorded in Aberdeen—viz., 15·1 per 1,000; and the highest in Paisley—viz., 27·6 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 5·2 per 1,000, or a slight increase on that for last week. Scarlet fever appears to be on the increase in Edinburgh. Acute diseases of the chest caused 65 deaths, or 10 more than the number recorded during the previous week.

ACCIDENTAL POISONING BY ACONITE.—Mr. James Lindsay, Bank Agent in Broughty-Ferry, was accidentally poisoned on the morning of the 8th inst., under the following circumstances: "Mr. Lindsay, who was about 70 years of age, went to bed between 10 and 11 o'clock the previous night. Being troubled with a cough, he rose and took a teaspoonful of a liquid, supposing it to be paregoric. Unfortunately it proved to be aconite-liniment. Mr. Lindsay died two hours afterwards. Deceased was highly respected, and was a son of the late Provost Lindsay, of Dundee.

ABERDEEN—DEATH OF DR. SIMPSON.—Dr. James Simpson, Aberdeen, a rising medical practitioner, died in Aberdeen on the 10th inst. after a comparatively short illness. The deceased was educated at Aberdeen University. He was one of the most distinguished students of his time, and carried off a large number of valuable prizes. He graduated at Aberdeen M.B. and C.M., in 1876, and received at the same time the Murray Gold Medal as being the most distinguished student of his year. He held some time since the appointments of one of the physicians to the Aberdeen dispensary, medical attendant to the workmen employed at the Corporation gasworks, and surgeon to the Aberdeen Engineer Volunteers. He took a prominent position on the Liberal side in the election of the Lord Rector of the University. Recently he took the first place in a competitive examination for appointments in the Indian Medical Service. About six weeks ago Dr. Simpson, along with a number of friends, was out on a boating expedition on Southampton Water. The boat, in which the party was, got stranded on a bank of mud. During the night Dr. Simpson fell asleep, and caught cold while lying in the boat. Malarial fever supervened, and this induced an inflammatory affection of the heart from which he died. General regret is expressed at the untimely close of a career which promised to be one of rare usefulness.

ANDERSON'S COLLEGE, GLASGOW.—The Chair of Institutes of Medicine at this School has become vacant through the resignation of Dr. D. C. McVail. Applications for the Chair will be received up to the 20th inst. To strong young men, with the "sacred air-cities of hope" still in prospect, and capable of undergoing the physical strain of canvassing some four-score bumptious tradesmen, and with sensibility not easily perturbed, a chance is thus presented of being elevated to the dignity of "Professor." A knowledge of the humiliation which such a canvass means, and the amount of collateral and underhand toadying required, would make anyone desire that the patronage of such chairs as this should be, in the gift of one individual, or that canvassing by friends or otherwise be strictly prohibited.

Obituary.

DR. W. O'CONNOR, LONDON.

WE announce, with regret, the death of Dr. W. O'Connor, Physician to the Royal Free Hospital, which took place at his residence, 30 Upper Montague Street, on the 2nd inst.

He appeared, on the morning of his death, to be in his ordinary state of health, but on walking home from his club in the evening he was suddenly seized with signs of exhaustion, reached his house with difficulty, and expired almost immediately he had entered it. We are unable to state the precise cause of his death, but during the last few years he had suffered severely on one or more occasions from some affection of the chest.

Dr. O'Connor was painstaking, and, when in health, indefatigable in the discharge of his hospital duties. His long connection with the RoyalFree Hospital afforded large opportunity for clinical observation. His actual contributions, however, to practical medicine were not numerous; they consisted principally of papers in the "Transactions of the Pathological Society" and the several medical periodicals.

DR. GEORGE ROBINSON, DUBLIN.

WE have to record the death, on the 9th instant, of Dr. George Robinson, formerly dispensary medical officer at Blessington, in the county of Wicklow, who, for some years past—since his retirement from practice—was well known in Dublin medical circles. Dr. Robinson was one of the past generation of Irish surgeons, and one of the most genial and most respected medical men of his time. He commenced his professional career under the guidance of the first Dr. John Jacob of Maryboro', and as the companion of Cusack, Graves, Arthur Jacob, and many whose names are household words in the profession. He took the M.B. of Dublin University and the Fellowship of the Irish College of Surgeons in 1830, and shortly afterwards settled in Blessington, where he practised for over thirty years. In his own country he achieved so high a regard as to be well-nigh indispensable as a family physician of the leading families of the county, and, in many instances, as their intimate friend; and when he retired from practice, and migrated to Dublin, he left behind him regrets heartfelt and universal. His success as a provincial practitioner was complete, yielding him a handsome independence; at a ripe old age he has succumbed to a sudden access of syncope, serene in mind and loved by those about him. He leaves behind him few of as generous and genial a spirit as his own

THOMAS BLAKE TURNER, F.R.C.S.I.

WE regret to have to announce the death of this gentle man, which took place at his residence, St. John's Abbey, Tuam, after an illness of some duration. Dr. Turner was a Fellow of the Royal College of Surgeons, Ireland, since 1845, and a Licentiate of the King and Queen's College of Physicians, and was Medical Officer of the Tuam Union workhouse, dispensary, and fever hospital.

Dr. Turner enjoyed a very extensive private practice in the county of Galway, where he was connected with some of the leading families.

Correspondence.

THE "PRIVATE INQUIRY" INSURANCE OFFICES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Oblige me by publishing the enclosed letter addressed by me to the Secretary of the National Provident Institution of Gracechurch street, London.

Yours, &c.,

23 Ely Place, Dublin, A. H. JACOB.
Sept. 4, 1860.

[COPY.]

"SIR,—I am favoured with your circular note offering me a fee of 10s. 6d. for replying to seventeen queries respecting the health of Mr. ——, and for advising your Company as to his eligibility for insurance. You are furthermore pleased to assure me that the information which you expect me to afford 'will be considered strictly confidential,' from which statement, and from the fact that I have received no communication from Mr. ——, I conclude that I am asked to report to you as to his state of health without his knowledge. I have the honour to decline the duty which you propose to me, and the fee which you think fit to tender, and I regret that you seem to have so little appreciation of the honourable relations between a physician and his patient as to propose that I should be guilty of the breach of confidence which you ask me to commit.

"If I felt myself at liberty to play the spy upon my patient for the information of your Company I should cer-

tainly not do so for the fee of half-a-guinea, and I entertain too high an opinion of my profession to believe that you will find any of its members, whose opinion is entitled to any respect, ready to do so.

"Yours, &c.,

"A. H. JACOB, M.D., F.R.C.S.I.

"Henry Rance, Esq."

VACCINATION METHOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I differ seriously in opinion from your leader on the Vaccination Method in your issue of September 8.

The Local Government Board is not a teaching body, nor are any of its members or officials of that very high professional status that they are to be looked on as instructors of such power as to interfere in this matter with the independence of medical officers in the practice of their profession. If the licensing bodies had done their duty such instruction would not be required; if required, the Local Government Board has not done its duty in seeing that those whose appoint ments they have sanctioned were duly qualified for such a defined duty as that of vaccination.

It is on a par with the attempt to teach the profession by lame circulars in 1849 how to treat cholera, and the Local Government Board might as well now try to enlighten us in the treatment of scarlatina or typhus fever.

When I remember how the founder of the *Medical Press* stood out for the liberty of medical officers during the outbreak of ophthalmia in the poor-houses, I regret to see it now take such a different line. As a fact, vaccination is performed well in Poor-law dispensaries, and this circular is no more than waste paper, but will often put the medical man in a false position, when lay people will think that he is not performing his duty if he deviate the least from the course laid down. If the Board had issued the 3rd and part of the 4th paragraphs as positive orders there might have been good reason for so doing, but as to teaching medical men how they are to scratch an arm and not to wet ivory points (a point in which I differ in opinion), is really meddling too much in duties better left to the previous knowledge and good sense of the practitioner.

I am, Sir, your obedient servant,

September 8, 1880. JOHN MARTIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the "Instructions to Vaccinators" lately issued by the Local Government Board, it is recommended that in vaccinating four incisions about one inch apart should be made. I doubt if many medical men could be got to agree with the above, and those to whom I have spoken on the matter are of opinion that four incisions or operations are wholly unnecessary, unjustifiable, and impracticable.

For my own part I believe that more than two incisions should never be made, and I consider one properly made incision covering a fair amount of space sufficient for all practical purposes.

I remain, your obedient servant,

RICHARD O'KELLY,
Medical Officer, Clonbrock Dispensary District,
County Galway.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

AN EYE-WITNESS.—For obvious reasons we cannot insert your letter but if you will furnish us with names and authenticated particulars we will have the matter investigated.

PATER.—Our next number will supply all the information you require. We cannot undertake to recommend any particular school; you will find the announcements of all in our columns next week. The two institutions mentioned in your note are fairly good, but there are better.

DR. THOMAS.—A similar case was under the care of Dr. Habershon at Guy's a short time since with favourable issue. Your treatment is the only rational one under the circumstances, but the result is always problematical.

EXAMINATIONS IN SANITARY SCIENCE.—We are asked by Dr. Anningson to announce that the next Examination in Sanitary Science at the University of Cambridge will begin on October 5. Candidates (whose names must be on the Medical Register of the United Kingdom) should send their names to Prof. Liveing, Cambridge, before September 25.

A CANDIDATE.—A Naval Medical Warrant has been long since promised, but is still *in nubibus*, and likely to remain there until agitation forces the authorities to move.

VACANCIES.

Baltinglass Union Workhouse.—Medical Officer. Election not fixed.
Cambrige County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board. Applications to F. M. Francis, 17 Emmanuel Street, Cambridge, by Sept. 27.
Cheltenham General Hospital.—Junior House Surgeon. Salary, £60, with board and lodging. Applications, with testimonials, before Oct. 10.
Ch ester General Infirmary.—Visiting Surgeon. Salary, £80, with board and residence. Applications to the Chairman of the Board before Sept. 27.
Evelina Hospital for Sick Children, London. House Surgeon. Salary, £70, with board. Applications, with testimonials, on or before Sept. 21.
Galway Union, Oranmore Dispensary.—Medical Officer. Salary, £120, with fees, &c. Election, Sept. 20.
Leeds Union.—Assistant Medical Officer. Salary, £100, with board. Endorsed applications to the Union Offices, East Parade, Leeds.
Martley Union, Worcester.—District Medical Officer. Salary, £50, with the usual extra fees. Immediate applications to the Clerk, 14 Forgate Street, Worcester.
Queen's College, Cork.—Professor of Surgery. Election, Sept. 30.
Witney Union.—Medical Officer. Salary, £144, with the usual extra fees. Immediate application to the Clerk, Witney, Oxon.

APPOINTMENTS.

ARCHER, R. S., A.B., M.B., Honorary Physician to the Fever Hospital. Liverpool.
BROWNE, R. J., L.R.C.S.I., House Surgeon to the Mater Misericordiæ Hospital.
CASHIN, J., L.R.C.S.I., Medical Officer to the Ardmore Dispensary, Youghal Union.
DUNBAR, A., M.D., Honorary Physician to the Fever Hospital, Liverpool.
GREVES, E. H., M.B., Demonstrator of Anatomy in the Liverpool Royal School of Medicine.
ROBINSON, J., M.D., Certifying Surgeon for the Turton District.

Marriages.

BARKER—DELMEGE.—At St. Peter's Church, Dublin, Arthur Edward J. Barker, F.R.C.S., to Emilie Blanche, youngest daughther of the late Julius Delmege, Esq., of Dublin.
PARISH—ANDERSON.—Sept. 9, at Christ Church, Erith, Kent, F. Parish, L.R.C.P., M.R.C.S., to Emma Frances, daughter of W. Anderson, Esq., C.E., of Erith.
POLLOCK—MEREDITH.—Sept. 2, at St. George's Church, Dublin, John Pollock, L.R.C.S.I., L.K.Q.C.P.I., to Isabella Agnes, younger daughter of Wm. Rice Meredith, Esq., Solicitor.
WHITTY—HEARNE.—Sept. 7, at St. Andrew's Church, Dublin, Patrick J. Whitty, L.K.Q.C.P.I., to Maggie, daughter of the late William Hearne, Esq., Waterford.

Deaths.

AMPHLETT.—Sept. 9, at 40 Weymouth Street, London, Edward Amphlett, F.R.C.S., younger son of the late S. H. Amphlett, in his 32nd year.
BURROWS.—Sept. 8, at Ivy House, Liverpool, Elizabeth, wife of Dr. John B. Burrows, in her 82nd year.
HUGHES.—Sept. 1, suddenly, Robert Hughes, M.R.C.S., The Red House, Woodbridge, Suffolk, aged 40.
MOORE.—Sept. 4, at 2 Osborne Terrace, South Circular Road, Dublin, Malcolm Henry Moore, M.B., aged 23.
ROBINSON.—Sept. 9, at 9 Elgin Road, Dublin, George Robinson, M.D., after a few hours illness.
SEYMOUR.—Sept. 8, at Baltinglass, co. Wicklow, Wm. Frederick Seymour, L.R.C.S.I., aged 40.
TURNER.—Sept. 7, at Tuam, co. Galway, Thos. Blake Turner, F.R.C.S.I., aged 67.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 22, 1880.

STUDENTS' NUMBER.

PART I.—The future of the Student in Private Practice or the Public Services.

PART II.—The Education and Qualification of the Student in the United Kingdom.

PREFATORY.

It is four years since our observations prefatory to the "Students' Number" predicted a revulsive change in the law of the medical profession, and, with it, a complete revolution in medical teaching and qualification. The change has not come, but it is coming, and would have been decreed before this but for the *bouleversement* which overtook Parliament and the Ministry during the last Session. When the Medical Reform Act passes—and it is certain to do so sooner or later, in spite of every obstructive counter-influence—the examining functions of every licensing body in the Kingdom will be swept away, our "Students' Number" (as hitherto understood) will cease to exist, and all students will thenceforth be obliged to pass a central examination uniform throughout the Kingdom.

We acknowledge with gratification that, under the influence of competition and of the demand for a thoroughly educated practitioner, medical education has, within the last and previous years, been "looking up." The old perfunctory method of pseudo-education—the survival of the ancient corrupt apprenticeship system—is dying out, and gives place to a more lively hard-working system of training. The Medical Council has helped a little in this change, the licensing bodies have yielded to the necessity for the reform, and, as a result, some improvement has been achieved.

In the higher walks of the profession, an ever-extending spirit of research is manifest; and we can, as we did last year, point with pride to many of the works produced during the past academic year, in proof of the assertion that we retain our foremost place in the ranks of the scientists. Much has been accomplished in this way, especially in sanitation, and the perfecting of the system of preventive medicine; but immeasurably more, it must be said, yet remains undone; and, however great and earnest they be in intention or in act, the army of workers in the field of discovery in medicine, and improvements in surgery, will need continual fresh accession, and continual strong recruits. It is to them, to the students of to-day, the practitioners of an immediate future, that we address ourselves in this number of the *Medical Press and Circular*.

A "Students' Number," in our view, belies its title and its function if it only dishes up—crude and undigested—the official regulations of licensing bodies. We have tried to translate these into intelligible English, but have, in a greater degree, devoted our columns to the purpose of laying before the Student the plain unvarnished truth about his methods of study and his qualification, and about the medical world which is before him when he has become a full-fledged "doctor." We have tried neither "to extenuate nor aught set down in malice," and we trust we shall—when the perusal of our Journal is completed—be considered to have done our work honestly, and to have smoothed the path of the Student and of his guardian at the time of his probation. With this object we have given in our present issue merely the pith of the official regulations of colleges and public services, reserving our space for practical advice and information which every Student needs, and leaving our readers to obtain for themselves the official regulations in a more reliable form than we can offer it. We conceive it to be our *rôle* to place in the hands of the Student and his guardians the semi-confidential details, directions, and hints which college regulations are not intended to communicate, and which are only known to those conversant with the various systems of education, examination, and qualification, and with the ultimate prospects of the Student.

PART I.

THE MILITARY AND NAVAL SERVICES.

THE ARMY MEDICAL DEPARTMENT.

The Royal Warrant, dated December 2nd, 1879, places this branch of the public service pecuniarily in a better position than it had previously enjoyed. The rates of pay under that Warrant are as follows, viz., Surgeon-General, £2 15s., or if at headquarters, £1,300 yearly: Deputy Surgeon-General, £2, at headquarters, £900 yearly; Brigade Surgeon, £1 10s. to £1 13s., at headquarters, £750 yearly; Surgeon-Major, £1 to £1 7s. 6d., according to length of service; at headquarters, £650. Surgeon, £200; after 5 years' service, £250 a year; after ten years' service, 15s. daily, equal to, say, £273 per annum. While on probation the surgeon receixes 8s. per day. Relative rank is as follows: as Major-General, Director-General, and Surgeon-General; as Colonel, Deputy Surgeon-General; as Lieutenant-Colonel, Brigade Surgeon, and Surgeon-Major after twenty years' service; as Major, Surgeon-Major of less than twenty years' service; as Captain, Surgeon; as Lieutenant, Surgeon on probation.

A candidate must possess two diplomas or licences, one in Surgery and one in Medicine; he must be registered. His age on appointment not to exceed 28 years. Appointments to be through public competition. Applications to be made to the Director-General. After appointment in rotation, a surgeon shall be sent to some large station for instruction in ambulance and hospital corps duties until the period of study begins at the Army Medical School. On passing satisfactorily through the latter he obtains his commission, the order of precedence being in that of merit at the final examination.

Promotion to the rank of Surgeon-Major to be after twelve years' service, three of which abroad; but for distinguished service promotion to be irrespective of seniority. To the rank of Brigade Surgeon promotion to be by selection for ability and merit, provided the Surgeon-Major has had eight years' foreign service in all. From Brigade Surgeon to Deputy Surgeon-General, and from the latter rank to that of Surgeon-General, promotion to be by selection. If appointed as Honorary Physician or Honorary Surgeon to Her Majesty, a medical officer, if under the rank of Deputy Surgeon-General, shall, if duly qualified, be promoted to that rank.

On completion of ten years' service a medical officer may retire on a gratuity or pension, if specially recommended by the Commander-in-Chief and Secretary of State for War. If retiring voluntarily before the age of 55, he is liable to be called upon to serve in the case of national emergency. A Brigade Surgeon, Surgeon-Major, or Surgeon, shall be placed on the retired list at 55 years of age. A Deputy Surgeon-General or Surgeon-General at 60. A step of honorary rank is obtainable on retiring after twenty years' full pay service. Exchanges are permitted. Good service pensions are granted in larger numbers than heretofore. Sick leave may be allowed for six months, and in special cases for a second period of the same extent—that is, a year in all. Temporary half-pay is granted under particular circumstances to medical officers incapacitated for duty by illness.

Some effective pay, or gratuity in lieu thereof is granted. To a medical officer of 10 to 18 years' service a sum of £1,250 to £2,500; Surgeon-Major from 20 to 30 years' service, £1 to £1 5s. 0d.; Brigade Surgeon, £1 7s. 6d. to £1 10s.; Deputy Surgeon-General, £1 15s.; Surgeon-General, £2.

Retired medical officers, and medical officers of the Militia, are eligible for employment up to the age of 65, receiving during the time of such employment a consolidated salary in place of retired pay.

THE INDIAN MEDICAL SERVICE.

The changes in the plan of administration of the medical service in India that has recently been introduced, in no way affects the terms of service in the Indian Medical Department as regards pay and pension.

1. Candidates for that service must be between the ages of 22 and 28.

2. May be married or single.

3. Must be registered as a practitioner, and possess diplomas in both medicine and surgery.

4. Must send a fortnight before the examination to the Military Secretary, India Office, a declaration (according to printed form), that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. His physical fitness will be determined by a board of medical officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed.

5. Must send wih the declaration—

a. Proof of age, either by his own sworn declaration (on printed form), or by extract from parish register. Baptism certificate not sufficient unless it affords proof of age.

b. Certificate of moral character from a magistrate or clergyman of candidate's church who has known him for at least last two years.

c. Certificate of registration.

Having received his diploma in surgery and medicine, the student is obliged to apply himself vigorously to the study of certain collateral subjects. He must perfect himself in chemistry, pathology, and comparative anatomy, and if he can throw a proficiency in botany and natural history, and French and German into the scale, he will materially improve his position in the scale of merit, and establish for himself a character with the authorities for industry and scientific attainments.

The examination usually takes place in February and August. The candidate will be examined in the following *compulsory* subjects: *a.* Anatomy and Physiology. *b.* Surgery. *c.* Medicine, including Therapeutics, the Diseases of Women and Children. *d.* Chemistry and Pharmacy, and a Practical Knowledge of Drugs. The Examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The *eligibility* of each candidate will be determined by the examinations in these compulsory subjects only. *Optional Subjects.*—Candidates who desire it will be examined in French, German, and Hindustani, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to Materia Medica; and the number of marks gained will be added to the marks in the obligatory part of the examination, and position on the list of successful competitors will thus be improved in proportion. The maximum marks allotted to the voluntary subjects will be as follows: French, German, and Hindustani (150 each), 450 marks; Natural Science, 300 marks. The subjects for this part of the examination will be taken from the following books: "Animal Kingdom," by W. S. Dallas, F.L.S. "Outlines of the Structure and Functions of the Animal Kingdom," by Rymer Jones, or "Cours Elèmentaire d'Histoire Naturelle," by Milne Edwards. Lindley's "School Botany," Lindley's "Medical and Economic Botany," Henfrey's "Elementary Course of Botany." "Elements of Natural Philosophy," by Golding Bird and C. Brooke. "Physical Geography," by Mrs. Somerville.

PROBATION AT NETLEY HOSPITAL.

The competitor who obtains a place in the ordinary service is obliged to undergo probation of four months at Netley Hospital, where he attends the following lectures: Pathology, by Dr. Aitken; Military Surgery, by Dr. Longmore; and Clinical and Military Medicine, by Dr. Maclean; Military Hygiene, Dr. de Chaumont; and Dr. Macdonald, on Naval Hygiene. The lectures on Military Surgery include gun-shot and other wounds; duties of army surgeons in the field, during sieges, on transport, &c., and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by diseases. The lectures on Hygiene relate to the examinations of water, air, food, and clothing &c., of the soldier, his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospitals under the Professor of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make post-mortem examinations, to operate on the dead body, and to pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues, and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's Service; he wears uniform, is under military discipline, and receives pay, as already stated. A sum of money equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks, the fortunate young man who wins this "Blue Ribbon of Netley" being tolerably certain to be well provided for.

Thus it will be observed that the first examination simply admits the candidate to the Service, and the conjoint result of it and the Netley examination determines his order of merit. Each candidate has to pay £5 towards the mess fund, one-half on his arrival and the remainder when he has passed his second examination. He is then a member of the mess, and entitled to dine at any time during the remainder of his service. The cost of dinner is 2s. 4d. daily, not including wine, and of breakfast from 10d. upwards.

Passage allowance to India on appointment will be given or a passage provided. When passages are provided on board the Indian troop-ships, a charge for messing will be made at the rate laid down in the Royal Passage Warrant of 1865.

Pay at 10s. a day will be allowed from date of passing final examination at Army Medical School.

Indian allowance and time of service for pension will reckon from the date of arrival in India.

Surgical instruments are provided in India by the Government for the use of medical officers.

The pay of medical officers in the Indian service is better than at home, and, if unmarried, the cost of living not greater. The Indian medical officer frequently holds lucrative civil medical appointments which afford him a handsome increase of income. To a healthy, temperate, unmarried man, the Indian Service is preferable to that at home, but to a delicate person, or one burthened with a wife and children, the advantages are questionable.

For officialregulations of the Indian Medical Service apply to the India Office, Whitehall, London, S.W.

NAVAL MEDICAL SERVICE.

The arrangements, time, and places for examination, the declaration to be made, and' documents produced, the subjects and method of examination, and the subsequent probation at Netley are to all intents exactly the same as those quoted above for the Indian Medical Service.

Having passed his examination and served at Netley, the candidate will receive his appointment as acting Surgeon to one of her Majesty's ships, either for service on board that ship, for or service on shore, at one of the naval hospitals—Haslar or Plymouth. He will be informed that he is granted two or three weeks, as he may require leave of absence, to enable him to provide his uniform and appointments. These he can get at any of the naval clothiers.

The expense of a Surgeon's unform is about £47 5s. The candidate must also provde himself with a set of surgical instruments, which will cost him from ten to fifteen guineas.

Fleet Surgeons to have the option of retiring after twenty years' full-pay service in all ranks at 15s. per day, and after twenty-five years, 21s.

Medical officers share in the proceeds of all *prizes*.

The following rates of pay and retiring allowances are granted under Admiralty Regulations, dated 7th October, 1875, namely :—

Full-pay Surgeons, from 11s. to 17s. per day, according to length of service. Staff Surgeons, £1 3s. to £1 10s. ; Deputy Inspector-General, £1 11s. to £1 18s. ; Inspector-General, £2 5s. to £2 10s. 6d.

Half-pay Surgeons, 6s. to 11s. ; Staff Surgeons, 11s. to 14s. ; Fleet Surgeons, 16s. to 18s. 6d. ; Deputy Inspector-General, £1 1s. to £1 7s. 6d. ; Inspector-General, £1 11s. to £1 18s.

Medical officers have rations according to their relative rank in the service.

THE CIVIL PUBLIC SERVICES.

POOR-LAW MEDICAL SERVICE.

A YOUNG qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from the inadequately remunerated appointment.

ENGLISH POOR-LAW MEDICAL SERVICE.

The English Poor-law Service differs in many respects from the Irish. Each parish in England and Wales has its guardians of the poor, and these parishes are grouped together to form unions. The unions are divided into districts for medical relief. Union medical officers therefore have the care of a district, and sometimes of a workhouse as well ; sometimes only a workhouse. He is elected by the guardians of the union, and the appointment confirmed by the Local Government Board. He must have both a surgical and medical qualification, and be registered, and is required to name a duly-registered practitioner to whom application can be made in case of his absence from home ; he can name his assistant or partner as his substitute. As a general rule, the guardians may not assign to any medical officer a district which exceeds in extent the area of 1,500 acres, or which contains a population exceeding 15,000 persons. This does not apply to Wales, but no such district may be assigned to a medical officer residing more than seven miles from any part of a parish included in such district. A medical officer is entitled to a fee of not less than 10s. or more than 20s. for attending a women in or immediately after childbirth, and to a fee of £2 where great difficulty has occurred in delivery, or long subsequent attendance has been necessary. Many of the salaries of Poor-law appointments are very low—often so out of proportion to the work done that the medical officer must give his services for nothing, or next to nothing, as he has to provide all medicines, instruments, &c., except trusses, cod-liver oil, and quinine, for which he sends a statement to the guardians, who pay him the cost price ; the paupers have to put up with those medicines which cost the least. In London and large towns some boards of guardians provide dispensaries, where the paupers are supplied with medicine, which relieves the medical officer from much labour and expense. It ought to be compulsory on all boards of guardians to provide dispensaries, and where this cannot be done, as in country districts, to provide all drugs, &c.

Capital operations, dislocations, fractures, midwifery, and vaccinations are paid for by a fixed tariff. The public vaccinator is appointed by the guardians. He must be connected with the parish work ; the candidate who has most interest is pretty sure of the appointment. The fees for vaccination are 1s. 6d. if performed at a workhouse or within a mile of the vaccinator's residence, 2s. between one and two miles, and 3s. over two miles. The guardians provide stations for vaccination where the vaccinator attends at stated times. He must be registered in medicine and surgery, and have obtained a certificate of instruction in vaccination, from a public vaccinator, authorised by the Privy Council ; he is required to transmit th ecertificates of successful vaccination to the vaccinating officer within seven days. Awards of not more than 1s. per case are given for successful vaccination of children up to six months, and are given on the report of the inspector to the Local Government Board if the marks are up to the standard, and the books properly kept. Only the relieving officers (and the overseers of the several parishes in cases of emergency) can give orders for medical relief. The relieving officer must inquire into the case, and, if necessary, visit the person before giving an order, unless the person is already on the pauper list. The medical officer can order nourishment and stimulants when necessary.

In England and Wales (more especially in the manufacturing districts) the medical practitioner derives much of his income from clubs, which pay him from 3s. to 4s. per head yearly, for which he visits and supplies medicines, &c.; the average payment for eaeh visit amounts to the large sum of about 6d. Small tradesmen, artisans, tenant farmers, labourers, &c., who would certainly be recipients of gratuitous relief in Ireland, are attended as private patients—of course, at lower charges than the better class of patients, and often either pay their bills by instalments or not at all. Parish appointments are often sought for by young men as an introduction to practice, or by older men to prevent opponents setting up in the district.

THE IRISH POOR-LAW MEDICAL SERVICE.

The newly-qualified medical practitioner who may elect to try his luck in the Irish provinces sets his hopes, in the great majority of instances, upon obtaining one or more Poor-law medical appointments in some district where there is hope of private practice. There are 163 workhouses and about 793 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service averages about £103 15s. ; and when it is taken into consideration that in the vast majority of rural districts, it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act passed in 1873 and amended in 1878.

The former office, in country districts, seldom yields more than £10 a year, and often not half that amount, and the emoluments of the latter appointment in very few cases reach £20 averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient his fee of 1s. (which has been raised to 2s. by the last Vaccination Act), is paid, along with his salary, by the guardians, and the sum total of these fees varies, according to the populousness of the district, from £2 to £50, an average for the provinces, under the old system, being about £5. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for— firstly, because they afford the new comer a certain, though hardly-earned salary, to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for practice into the field, and inasmuch as private income is of far greater import than public earnings, country medical practitioners are obliged to undertake the public duty in order to save themselves the monopoly of their private emoluments.

Appointment.—The qualifications required by the Poor-law Commisioners are a License in surgery or a Diploma in medicine, and a Diploma in midwifery; the candidate must also be 23 years of age.

The appointment lies with Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law medical officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required, and whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential; and, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away. We may here observe, also, that in very many instances the appointment is virtually made before the advertisement appears for a medical officer, in which case, also, candidates are put to unnecessary trouble and expense under false pretences.

Control.—Each district is under the control of a committee composed of the neighbouring landholders; the appointment of medical and other officers is made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Local Government Board, who have the power either of interposing their veto on any appointment, or even expelling an officer by a "sealed order," without trial or accusation, or without the resource of appeal or investigation. The salary is paid by the Board of Guardians, and no increase can be made in the amount without their assent and that of the Local Government Board. Under the late Sanitary Act the committee may recompense the medical officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The number of unions in Ireland is 163, to each of which is attached a medical officer, who is appointed and controlled by the Board of Guardians in the same manner as the dispensary surgeon is by his committee. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as the duties are confined to daily attendance at the workhouse hospital, and no night visits out of doors or any long journeys across the country are involved.

Duties.—The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the same. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependant on the goodwill of the members of his committee. If the medical man be a favourite with his masters, they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—aye, even to the committee man's own brother or daughter.

Superannuation.—A Poor-law medical officer may now receive a pension not exceeding two-thirds of his salary on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians; nevertheless, it has been given in most cases in which physical incapacity has been clearly proved. It is, however, at best a miserable resource, and can by no means be calculated upon as a provision for old age. There are now nearly 60 ex-medical officers receiving superannuation allowance, whose average term of service before pension was 20 years, and whose allowance is £64 15s. Their average age at retirement was 63. All official information may be obtained of B. Banks, Esq., Local Government Board, Custom House, Dublin.

Complete information as to fees, emoluments, duties, and appointment of Irish Poor-law medical officers will be found in the "Irish Medical Directory" for 1880.

THE SCOTCH POOR-LAW MEDICAL SERVICE.

To many young men, anxious, without the delay incidental to the making of a practice in a large city to realise an immediate income, and fond of a country life, the appointments held under the Parochial authorities of Scotland offer inducements. Practically these appointments, once made, are held *ad vitam aut culpam*, while in terms of the strict letter of the law, they are but yearly appointments. Arbitrary dismissal is, however, guarded against by the powers of the Board of Supervision. It is expected that soon Parochial medical appointments will be *legally* placed on the footing of permanent ones, and that a retiring allowance will be provided for the medical officers as is the case in Ireland. The emoluments received from the Parochial Boards vary according to the number of paupers, size of the parish, and often the local exigencies requiring the residence of a medical man. The salaries may be said to range, on an average, from £30 to £100 per annum. In remote and thinly-peopled districts the landed gentry and large farmers assess themselves in sums varying from £5 to £20, to make up an adequate income to the doctor, which however must be held in lieu of fees for medical attendance. Should such attendance, however, be much in excess of any such sum, the doctor is usually safe in trusting to the honour and generosity of the Highland gentleman, for this arrangement is more peculiar to the Highlands of Scotland. The young doctor has more speedy and easy access to "good society" in the country than in large cities; and perhaps better society than the latter; and should he be worthy of it, he is certain to command respect and courteous treatment, and with limited ambition and sporting tastes to lead an useful and happy life.

ASSISTANCIES, PARTNERSHIPS, &c.

MANY men, looking over the voluminous accounts of college curricula and university regulations, either for themselves or their sons, may naturally draw a deep sigh over the work to be done or the money to be spent, and exclaim, "What then?"—or, to quote Mr. Cobden's familiar expression, "What next, and next?"

Of course the full and complete reply to these questions would fill a volume or two; but we may briefly indicate what can and what cannot be done, *as a rule*. (a) There are many exceptions, but we advise no one to think that he will escape the general rules which affect the mass of men.

First, there is private practice as a destiny and ultimatum. In Ireland and Scotland it is generally found that private practice worth having only exists in large towns; elsewhere, in these two divisions, medical men live chiefly on their appointments. In England this is not so; the appointments are subordinate to the practice everywhere; the succession to a practice can be very generally secured by purchase; but this is not so in Ireland or Scotland. But in England there are practices which cannot be bought; no money will command the highest class of practice; it is a personal thing which attaches to a man, and cannot be transferred. Partnerships are regarded as safe introductions to practice, but apart from the notorious changes of partnerships, we regard them as greatly over-estimated in value. In considering a sphere for practice, the first question is the adaptability of the purchaser to what he contemplates. A suitable man will, as a rule, succeed to any practice where he is favourably and systematically introduced to the patients by his predecessors; but no man will undertake to resign his appointments and introduce a successor without a *quid pro quo*. Unless, therefore, a man has capital, he should not think of purchasing a practice.

A prevalent fallacy is that some man overworked wants a partner to relieve him of part of his work and—his income. If the practice is fairly good, the overworked gentleman can readily find a partner who will pay two years' purchase for the share secured. But some one wants to join him as a "working partner," and to pay nothing. Which is the overworked gentleman likely to accept—a junior partner, who will pay perhaps £1,000 for his share, and to whom he can delegate the greater part and all the drudgery of his work, or the junior who will do the same work, but will not pay the £1,000?

An assistantship is a capital discipline for any man. Such engagements are not what they used to be; the assistant in a medical practice being treated as a gentleman. But for details on this head we would refer to Langley's "Via Medica," which deals fully and fairly with this subject. No man should go out as an assistant without reading it, especially as it is to be found in nearly every college library.

Medical assistants may be divided into two classes, qualified and unqualified; but the salary which either will obtain is far more a question of actual experience than of the diploma which may be held in any given instance. The experience obtained by an assistant in England, even though unqualified, may be sufficient to enable him to obtain a far higher salary than many gentlemen of much higher qualifications, but without knowledge of English practice.

To act as "Locum Tenens" it is essential that previous experience of practice should have been obtained. Irish gentlemen, as a rule, are very deficient in dispensing, and the routine of English practice, which differs very materially from that which prevails in the sister isle, as medical men do not often dispense their own medicines in Ireland, and to this cause may in many cases be attributed the expression ofttimes seen, "No Irish need apply."

An assistantship, "with a view to partnership," is a thing that people read and write of, but seldom see. Experience shows it to be a mistake on both sides. If the assistant has money, he had better not appear in the practice as subordinate; if he has not, the probation will not as a rule assist him to get a share in the practice.

If, however, a successful student declines to enter private practice as purchaser or as assistant, he may enter the public services through the open doors of competitive examinations.

Practices abroad are rarely to be had or heard of. Sometimes they can be secured upon equitable terms; the contracts, however, should be always conditional upon the practice "out there" being found what it is represented to be. In such cases the intending purchaser should avail himself of the skill of some experienced and respectable medical agent.

In conclusion, it may be stated that whilst we have indicated generally the portals to success *after* the diploma has been obtained, we have no intention of ignoring the fact that men of decision of character, good antecedents and high qualifications, can and do secure distinguished positions in the profession, and occupy a large space in the eye of the world. But genius is the heritage of the few, and the great majority of men will do well to moderate their ambition, and seek to do their duty in the customary spheres of life in which many noble-hearted men have lived and worked and died, leaving the world somewhat better than they found it.

(a) For further information we would refer the reader to Langley's pamphlet, "Advice on the Transfer of Medical Practices, etc."

PART II.

EDUCATION AND QUALIFICATION OF THE STUDENT.

THE parent who desires to make a doctor of his son, or the student who selects that profession for himself, is probably already aware in a broad way of the steps which must be taken to effect this purpose. He knows that in order to practise medicine or surgery legally in Great Britain or Ireland it is necessary to be enrolled in the Medical Register, and that, to obtain that distinction, it is necessary to study at a College and a Hospital for about four years, and afterwards obtain one or more diplomas by passing one or more examinations in professional subjects.

The first point to be decided is whether the boy is of the proper age for studentship, and has received the requisite amount of schooling. As to the first of these points there need not be much apprehension, for although some of the licensing bodies profess by their regulations to accept for their diploma no candidate whose age is less than twenty-one, there is practically no minimum limit of age of the students. But circumstances impose some such limit, because none of the Public Services will appoint to medical office any youth of earlier age than twenty-one, and it is therefore not only useless, but unadvisable, to complete the student's education until he has reached that mature age. Moreover, in England, no student receives credit for any part of his medical study, as counting towards his diploma, until he has passed his preliminary examination in general education, and the average boy will hardly be able to do this until he has passed his sixteenth year. For these reasons the majority of students do not commence their medical studies until they are seventeen or eighteen years of age, in which case they receive their diplomas between their twenty-first and twenty-third years.

The second consideration is whether the boy has been sufficiently schooled, and this is determined by his capacity to pass a recognised preliminary examination in general education. Of such recognised examination the Medical Council publishes a list comprising most of the primary collegiate examinations throughout the world, but as to the extent and gravity of such examinations there are the most extraordinary variations. As a general rule the preliminary examination consists of Latin, English, and a moderate extent of Euclid, Algebra, and Arithmetic; occasionally modern languages and Greek, and also Natural Philosophy are added as optional subjects.

In England, and with most of the Scotch licensing bodies, it is essential that the student shall have passed his preliminary examination *before* he commences medical study. This is not the case in Ireland, where it is possible, though not usual, for the student to postpone his examination in general education until the eve of his professional examination. If he is either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his examination for qualification, when if he does so, he will find himself in possession of a mental muddle of Latin and physic. The preliminary examination is, however, not to be feared.

We strenuously advise the parents of the student to insist on his passing his preliminary education before he enters a medical school or hospital, and thus the student will relieve his mind of the apprehension of a future examination, which he will assuredly put off to the last moment if he can. In England the four years of medical study required to pass do not commence to count until the preliminary is passed. It should be so in Ireland, but it is not.

The preliminary examination having passed, it becomes necessary to select the method of education to be pursued. It should first be decided what is to be the aim of the student in after-life, for upon that question will depend in great measure the school at which his studies are to be pursued.

THE CHOICE OF UNIVERSITIES AND COLLEGES

Will depend on various circumstances, and on the aspirations of the student. If he is intended to make a fortune and enlighten his generation as a metropolitan practitioner, and if money and education are plenty, he will probably take University degrees in arts and in his profession. If the attainment of good professional rank on moderate terms be desired, the Licenses of the "College and Hall' for London, the Colleges of Surgeons and of Physicians for Ireland, or the Double Diploma of Edinburgh for Scotland, will serve every purpose. For any University degree which are of any value, it is to be remembered the student must undertake the prolonged study of classics and science in addition to his medical, surgical, and anatomical studies; and he will have to pay a considerable sum for this course of teaching. But if he is content to face the expense and labour, he will enter the profession with all the prestige of an educated gentleman. In fact, the question whether he will or will not lay out for himself a University graduation in arts or medicine, depends principally whether he has money and time to give to it, and whether or not he means to practise in the metropolis. The University of Durham, the Queen's University in Ireland, and some of the Scotch Universities place at the disposal of the student a cheap University degree, and thereby attract many applicants who are at liberty to write M.D. after their names, and are not called upon for any prolonged University residence or academic study. These degrees serve as legal qualifications to practise, and pass for an academic Doctorate in Medicine amongst the uninitiated; but do not confer the prestige attached to the degrees of Oxford, Cambridge, or Dublin.

If the student elects to seek a University degree—other than that of the London University—he will, of course, pursue his Arts study in Oxford, or Cambridge, or Dublin, and his professional studies *pari passu*. If he be content with simple licences to practise, he must attach himself to a School and Hospital. Here the English and Scotch systems differ widely from that in existence in Ireland. In London, the usual course is for the student to select a School which is suitable to his pocket and his locality of residence, and where he thinks he will get "good value." The School is almost always in immediate connection, and on the same premises as one of the hospitals. In Dublin, on the contrary, the Schools have no immediate connection with any hospital, and the pupils of a Dublin School are a heterogeneous gathering from all the hospitals in the city. In England a composition fee is accepted by many of the Schools, and is paid in one or more instalments, which fee entitles the student to the whole of the curriculum of lectures, dissections, hospital, &c., necessary for his diploma. In Ireland, on the contrary, the fee for every course of Lectures and for Hospital attendance is paid separately usually at the period when the certificates are required, *i.e.*, on the eve of the examination.

The following is a statement of the composition fee payable at each London School from the most expensive to the cheapest:—

Bartholomew's, Guy's, or University College	£131 5 0
King's College, St. Thomas's, or St. George's	125 0 0
St. Mary's	106 1 0
London	94 10 0
Westminster	92 10 0
Middlesex	90 0 0
Charing Cross	88 4 0
Birmingham Queen's College or Manchester Owens College ...	105 0 0
Bristol	99 0 0
Liverpool	86 2 0
Sheffield	81 15 0
Leeds	71 8 0
Newcastle	70 7 0

Diploma Fees not included.

These fees are close approximations, subject to addition for extras required for certain licenses. The fees may be paid in full at the entering of the student, or they may be paid in certain fixed instalments at the beginning of the successive periods of study, by which system the total payment is something larger than those above quoted. It will thus be observed that, in England the student is encouraged to enter at a particular school and hospital

and to take his whole education there, and, as a matter of fact, the great majority of students follow this course. It has its advantages, not the least of which is that it places the student under the absolute control of his teachers, and enables them to dictate his method of learning, and to supervise his diligence to a much greater extent than is possible elsewhere.

In Ireland, on the contrary, composition fees are a rare exception to the rule. The student goes to any school he pleases and any hospital he pleases, and enters his name for any number of lectures he pleases. If he does not like his school or hospital, he most probably migrates to a rival institution on the first opportunity. It is, in fact, but seldom that an Irish student confines his studies to a single hospital, and, in order that he may be perfectly free to seek his education where he thinks he can best obtain it, it has been recently decreed by the Dublin hospital surgeons that perpetualism be abolished, and that no discount be allowed to students in consideration of their taking out their entire time at one institution.

The Irish system is open to grave abuses, which need not be dwelt on at present; but it has certainly the great merit of rendering the student perfectly independent, and forcing schools to compete energetically for a continuance of his patronage. It will be obvious, however, that the system which enables the student to pay a lump sum, and thus relieve himself of the trouble of entering for lectures, and paying fees in detail, is a convenient one, especially for the beginner, who is altogether ignorant of the system, and therefore the requirement which is provided for in England by the dean of the school, is met in Ireland by individual teachers or "apprentice" holders.

COST OF EDUCATION IN IRELAND.

Should the student proceed on his own account, the lectures necessary for the diplomas of the Colleges of Physicians and Surgeons in Ireland will amount to £65; hospital attendance, according to the new scale of fees, £36; lying-in hospital, from £4 4s. to £7 7s. These, with the diploma fees of £26 5s. for the College of Surgeons, and £15 15s for the College of Physicians represent the essentials. Thus, the absolute payment will amount to somewhere about £93, taking the minimum mode of payment. In addition to this sum are to be considered the payment for "grinding" or "coaching," a process almost universal, but by no means necessary to any industriously inclined student. The fixed sum is at present for private teaching £15 15s. for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So that, assuming the extras or voluntary costs are incurred, the total will vary, say from £120 to £140 on a moderate scale; it is, of course, to be expected that pupil holders should have some extra payment; we therefore might name for them 160 guineas.

This sum, or something like it, will secure to the pupil the advantage of being "apprenticed" to a teacher who will undertake all monetary responsibility for his education, and may be able to give him some special advantages as his own pupil at hospital; but it must, we fear, be confessed that the so-called apprenticeship is sometimes a simple contract for payment of fees, and involves but little of that special teaching which is due by a master to a true apprentice. Most of the apprentice holders will accept payment by instalments.

PAYMENT OF FEES.

If the student is his own manager, he must enter his name with the secretaries of the school and hospital, and pay for the lectures and hospital he intends to take out. If he is wise he will not adjourn the majority of his lectures, as he may, to the next year, but will take in his first year a full third of his curriculum. He is *supposed* to pay the professor's fee or hospital fee in full on entering his name, but few students do so; and many, we are sorry to say, are in the habit of entering for the minimum allowable number of lectures, and paying the minimum allowable proportion of the fee, putting off the attendance perhaps for ever, certainly until the last moment, and adjourning the payment until it becomes necessary to take up the certificates.

By a most objectionable laxity of system a student may get credit for one of his four years of attendance by paying a couple of guineas for dissections, and he may think himself safe in doing so if money be scarce; but if he does not pay his full third or fourth of the fees each year it often happens that he has to put off his examination from year to year—perhaps for ever—for want of money to pay the accumulated fees of previous years.

REGISTRATION OF STUDENTS.

Having thus entered his name as a medical student, and acquired his right to commence study, his next business is to register himself as such on the General Medical Council.

To this body is entrusted the supervision of Medical Education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do with the Council, except that he must take care to be duly registered as a Student in Medicine, *at the commencement of his career*, at the offices, 315 Oxford Street, London, or at the offices of the Branch Registrar of the division of the United Kingdom in which he is residing. He must in England previously have passed a preliminary *Arts Examination*. With regard to registration, each English student should apply according to a form, accompanied by a certificate, of his having passed such examination, the same to be lodged with the Registrar, who will thereupon enter the same in the Students' Register, and issue a certificate to that effect. It should be recollected that this commencement of the course of professional study is not reckoned as dating earlier than fifteen days before the date of registration.

The intention of this registration is to ensure that the student shall occupy four years in medical study, which is, theoretically, the period which must be devoted to his education before his entry to the profession. In England this requirement is set down as essential, and no student can present himself for examination sooner than four full years from the date of registration, but the obligation to occupy this period in medical study is frequently satisfied by a nominal service for the first year under a general practitioner, or in a provincial hospital or dispensary, and the actual period of medical study is often really three years. Besides, the standard of medical education, as well as of the examinations of various examining bodies, is so much higher than it formerly was, while our own knowledge of medicine and the collateral sciences, and the scope of our medical studies have recently become so enlarged that four years is by no means too long a period to be devoted to medical study; and even the diligent student will find that at the expiration of this term he will have but an imperfect acquaintance with several branches of his profession.

In Ireland the registration of medical students is very irregular and unsatisfactory. No pupil thinks of giving himself any trouble about the matter, and leaves it to the Registrar of his School to return to the Branch Medical Council the names of his *alumni* which, for reasons the initiated understand, he frequently forgets to

do. Inasmuch, therefore, as there is, in Ireland, no legal date for commencement of medical study, there is no means of judging whether the nominal four years of medical study are, or are not, actually occupied in learning the profession, and, as a matter of fact, few students do devote that period to their work, though many of them continue in the nominal study of medicine for as long as seven or eight years.

DATES OF ENTRY IN IRELAND.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the Session really does date from the 1st of November, and the entry of names may be delayed by the dilatory until the 25th of the same month.

The student then begins work, attending hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and dissections. His holidays—if the term be not ignoble—are a fortnight at Christmas, and a week at Easter, and he finally returns home at the end of July.

LECTURE ATTENDANCE IN IRELAND.

The average Dublin student is supposed to attend of necessity, and irrespective of voluntary courses, twelve courses of lectures, six of them extending over six months, and six over three months, making a total of 52 months lecturing. In addition to this, he is presumed to dissect and hear demonstration, say an hour-and-a-half daily, for eighteen months, to attend hospital for at least a couple of hours daily for twenty-seven months, to serve in the chemical laboratory for three months, and in the majority of cases to attend the "grind" for at least eighteen months for two more daily hours. He cannot, if moderately industrious, get on with less than two hours reading per day, and he may have during the same period to work up his business for the "Preliminary," or his Arts Course in the University. This curriculum—taking the lectures on an average of four days weekly—represents nearly five thousand hours close work to be got through in three working years of about seven months (allowance being made for Christmas and Easter and summer holidays).

Thus it will appear that the student, to fulfil the *nominal* requirements of his education in Dublin, must work very nearly nine hours daily—*i.e.*, from after breakfast to about seven p.m. It is hardly necessary for us to say that even the most avaricious medical bookworm does not attempt such a task. Necessarily the attendance on many of the courses of lectures is nominal in amount. The University of Dublin insists on an attendance of three-fourths of the number of the required lectures, but other licensing bodies accept as "diligent" attendance the presence of the student at all—a few—or none of the lectures which the student pays for. It would be manifestly ridiculous for them to demand *bonâ fide* compliance with the regulations, and thus it happens that the student being hopeless of attending at all, often attends scarcely any of the lectures which are supposed to form the chief part of his education. The average student thinks himself exemplary if he works his hospital, dissections, demonstrations, physiology lectures, and grind, and drops in occasionally to the other courses.

The progress of each year is the same, except that he usually devotes more attention to the "grinding," dissection, and hospital dresserships, and less to lectures in his later years of study. At the end of his second year he will take his "first half" examination, and by so doing relieve himself, in a great measure, of the study of anatomy, and be in the position of devoting his third year to surgery and medicine. After the expiration of his third session, his student life, whether it begin in laziness and end in a hurry and incompetency, or whether it commence in diligence and end in the confidence of proficiency, ends with the last examination, and he goes forth into the world either an ignoramus or a reliable surgeon, whichever his choice may have been.

THE STUDY OF VACCINATION IN IRELAND.

No candidate for an Irish qualification is now admitted to examination without producing a certificate of attendance for one month at the Cow-pock Institution, or under the instruction of a public vaccinator.

The instruction should include—1. The performance of the operation of vaccination. 2. The conditions of the patient which contra-indicate vaccination. 3. The characteristic appearances of the vaccine disease at the different stages of its course, and the deviations therefrom, which are compatible with its protective influence. 4. The taking of lymph and the method of preserving it in tubes or on points; and of recognising impurities. The candidate is examined upon these subjects at his final examination.

FINAL REGISTRATION OF PRACTITIONERS.

All duly qualified persons are required by the Medical Act to be registered before they can hold any public medical or surgical appointment, or issue valid medical certificates.

The medical registration of any practitioner is effected on personal application or in writing (according to a form to be had in London or at either of the Branch Offices). With such application he must produce or transmit the *Diplomas*, and also the fee, £6 for the first registration, and 5s. for every qualification which may be subsequently added.

THE UNIVERSITIES.

THE great majority of medical students in past years have been content to pursue their professional avocations without obtaining the additional distinctions conferred by University degrees. The present generation, however, is, in this respect, more ambitious, and a large number of young men are at this moment engaged in fulfilling the requirements of the statutes by which the conference of bachelors and doctors' degrees in medicine and surgery are regulated. The indication this affords is highly gratifying, as showing the increased appreciation of the wider culture insisted on by the Universities ere they will recognise the fitness of any candidate for their diplomas. In all places the conditions of graduation are not the same, and in these pages we shall briefly indicate the principal features of each of the great centres of learning. In all, however, there is one essential resemblance, consisting in a rigid enforcement of the rule requiring intending competitors for medical degrees to show a preliminary acquaintance with the main branches of higher general education. The medical man cannot be too well educated; he cannot be too widely read; and especially ought he to have familiar acquaintance with the outlines of that complex study to which by general usage the term, "natural science" has been applied.

Oxford.

The medical degrees of this University, the small number of which hitherto in use has been an approbium on its efficiency as a school of medicine, are now being sought at an increasing rate each year; but it cannot be any considerable proportion of medical students who will join them, because of the conditions which have to be complied with to that end.

Every student in medicine must pass all the examinations for the degree of B.A., and date the commencement of his medical studies from the final examination for arts. For the degree of B.M. two examinations must be passed, the first including Anatomy and Physiology (Human), Comparative Anatomy (chiefly the entozoa), and Physiology, Botany, Chemistry (theoretical and practical), and Physics, with Mechanics. At the second examination he is examined in two of the ancient authors—Hippocrates, Aretæus, Galen, and Celsus—and in some one modern author, as Morgagni, Sydenham, or Boerhave. He must spend two years in study prior to the first or scientific examination, and two years more after passing the first, prior to the final examination for the same degree. A dissertation has to be publicly read three years after obtaining the M.B., before being eligible for the M.D. The medical examinations take place annually in Trinity, but in 1880 there will be also an examination in Michaelmas term about November 29.

Scholarships of value from £60 to £100 are obtainable

Christ Church, Magdalen, and other Colleges, by competitive examinations in natural science. Each year a Radcliffe travelling fellowship is competed for by anyone who, having taken a first-class at any of the public examinations of the University, or having obtained some University prize or scholarship open to general competition, proposes to graduate in medicine. The travelling fellows receive £200 a-year for three years, half this period being spent in study abroad.

The facilities for the study of medicine at Oxford are considerable, but unfortunately no attempt to utilise them is made or encouraged. It may be hoped, however, that this will, ere long, be entirely altered, and that Oxford may rank at least with Cambridge as a centre of medical education.

Cambridge.

At the University of Cambridge, five years of medical study are required, unless the student has graduated with honours as B.A. For the M.B. he must have resided nine terms in the university, and have graduated in arts. There are three examinations for this degree. The first is in chemistry, physics, and botany; the second, in anatomy (human and comparative), physiology, and pharmacy; and the third, in the usual practical subjects. Subsequently to the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations, and an essay has to be written *extempore*. There is also a degree of Master in Surgery, for which the candidate has to attend extra courses of lectures on anatomy and surgery. An examination in so much of State Medicines as is required by medical officers of health, will in future be held. With respect to Cambridge (and almost the same apply to Oxford), a residence during nine terms—*i.e.*, the greater part of each of three years—is by statute requisite to obtain any degree in arts, medicine, or any other subject. The actual cost of this to a student who keeps his terms by residence in a college is from £150 to £200 a year. This, however, may include all payments to the university and the college—all fees, as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the university fees, which are very small. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

London.

The candidate for the University of London Degree in Medicine is hampered by no restrictions regarding sex, residence, instruction, or nationality. The only conditions necessary to be fulfilled are those contained within a diversified curriculum. "Matriculation," an examination which derives its difficulty from the number of subjects included in it, must be passed before the commencement of medical study. It is usual to rate the London Degree as a high one; this it is, in the sense that much reading of deep books is needed to secure it; but it may fairly be doubted whether the fancied superiority claimed for it has not been somewhat over-estimated. That man, whencesover his qualification has been derived, who loves his profession for its own sake, will advance in it, and by it, it is surely time we heard the last of this or that body's superiority in a *medical* sense, and it is quite possible to accord all legitimate admiration for the greater degree of general cultivation distinctive of the holders of various university degrees as evidenced by such degrees; but the assumption that goes with it that the elements of technical education are more embodied in some than in other examining boards' schemes, is an unfair aspersion of the schools which are the first sufferers. All will admit, however, that the best trained practitioners are such as have enjoyed the most liberal opportunities of general culture, when this has been introductory to the study of medicine. The University of London, therefore, is a serviceable corporation, in that it offers facilities *to all* to put the hall-mark of a University degree on their attainments.

Those students who intend to graduate at the London University arrange their studies as to pass the preliminary scientific examination *before commencing their regular medical studies*, taking a preliminary year for the purpose of preparation. In this way much knowledge will be gained which will go to clear the way for his first year's studies, which would otherwise be much encumbered.

The preliminary ssientific examination commences on the third Monday in July, and no candidate is admitted to it unless he has completed his seventeenth year, and has passed the matriculation examination. The subjects on which he will be examined, are—Inorganic chemistry, experimental physics, botany, vegetable physiology, and zoology. Candidates who shall pass in all these subjects, and shall also pass at *the same time* in the pure mathematics of the first B.Sc. examination, or shall have previously passed the first B.A. examination, shall be considered as having passed the first B.Sc. examination. There are in this, as in every other stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches, such as valuable scholarships, exhibitions, and prizes. The medical and scientific degrees of the University are—Bachelor and Doctor of Medicine, Bachelor and Master in Surgery, and Bachelor and Doctor of Science. For the regulations respecting these examinations the student should apply to the Registrar of the University.

It has come to be generally felt that scientific knowledge, to be real, must be practical as well as theoretical, and that a thorough knowledge limited to a comparative small range is preferable to a slighter acquaintance spread over a more extended area. In the first examination for Bachelor of Science, which every candidate will be required to pass, the programmes in mathematics, experimental physics, and inorganic chemistry, have been carefully revised. In place of the superficial acquaintance with both zoology and botany formerly required at this examination, there is a single examination (written and practical) in general biology, in which a more thorough knowledga is required of the simplest forms and elementary phenomena of animal and vegetable life. The regulations for the second B.Sc. examination, on the other hand, are framed with the view of allowing the candidate to bring up any three of the following nine subjects:—(1) Pure mathematics, (2) mixed mathematics, (3) experimental physics, (4) chemistry, (5) botany, including vegetable physiology, (6) zoology, (7) animal physiology, (8) physical geography and geology, (9) logic and psychology. Moreover, in the matricular examination which forms the basis of the science curriculum, German may now be taken in substitution for Greek. In regard to the Doctor's degree, a change has been made in favour of candidates who prolong the interval between their first and second examinations for the degrees of Bachelor from one year to two or more, as such will be allowed to come up for the degree of Doctor of Science within a year of their attaining the degree of Bachelor.

A special examination is held once in every year in subjects relating to public health, to which those candidates only are admitted who have passed the second M.B. Examination at least one year previously. Candidates will be examined in chemistry and microscopy, as regards the examination of air, water, and food; meteorology, geology, physics, and sanitary apparatus, vital statistics, hygiene, and sanitary laws, full particulars of which may be obtained from the Registrar.

All the medical degrees of the London University are open to women, and valuable scholarships have been founded for their special benefit.

University of Durham.

Two licences and three medical degrees are conferred by this university—viz., Licences in Medicine and Surgery, with degrees of Bachelor of Medicine, Master of Surgery, and Doctor of Medicine. A certificate of proficiency in sanitary science is also awarded.

With regard to the degree of Bachelor of Medicine, no one will be admitted to that degree unless he has kept one year's residence at the Durham University College of Medicine, and in the case of non-university men an additional arts examination to the professional examination must be passed. There are two professional examinations for the M.B., the first being held twice yearly in October and April, and the second twice yearly in December and June. In the year 1880-81 the first will commence on October 4th, 1880, and again on April 25th, 1881, and the second on December 6th, 1880, and again on June 13th, 1881.

No grace for the degree of Doctor of Medicine will be granted unless the petitioner is a Bachelor of Medicine of the standing of twenty-one terms (seven years) at least from his registration or matriculation, and of two years at least from his admission to the degree of Bachelor of Medicine, nor unless he has written an essay based on original research or observation on some medical subject selected by himself, and approved of by the Professor of Medicine.

For the degree of Master in Surgery the candidate must have passed the examination for the degree of Bachelor in in Medicine, and must have attended one course of lectures on Operative Surgery. Each candidate will have an additional paper on surgery, and will have to perform operations on the dead body, and to explain the use of instruments.

There is also an examination and a certificate of proficiency in sanitary science. Hospital practice can be attended at the Newcastle Infirmary, which contains 230 beds. There are four scholarships of £25 a year, tenable each for four years. Dickinson Memorial Scholarship, £15, tenable for one year, for general proficiency. Tulloch Scholarship, £20, tenable for one year, for anatomy, physiology, and chemistry. Charlton memorial scholarship. £35, tenable for one year, for medicine. Gibb scholarship in pathology, £20, tenable for one year. Four resident dressers, who also act as physicians' clinical clerks, are chosen every six months from the senior students. Fee for six months' board and residence, £10 10s. Two assistants in the pathological department are chosen every six months. At the end of each session a silver medal and certificate of honour will be awarded in each of the required classes.

An examination will commence on December 6th, 1880, and again on June 13th, 1881, in the College of Medicine, Newcastle-upon-Tyne.

With regard to fees, a composition fee for all the Lectures, payable on entering to the first winter session, £52 10s. Separate courses of lectures each, £4 4s. Twelve months' hospital practice, £7 7s. ; six months, £5 5s. ; three months, £4 4s. ; perpetual fee, £17 7s. ; or, if paid by instalments, first year, £7 7s. ; second year, £6 6s. ; third year, £5 5s. These fees also are payable in advance.

Foreign Universities.

An essay on "Foreign Degrees and How to obtain them," giving information much sought for, but not readily obtainable in this country, together with the routes and fares to, and from, the different university towns of the continent, appeared in the *Medical Press and Circular* for October 1, 1879.

Royal College of Physicians.

The license of the Royal College of Physicians, which is recognised by the Local Government Board as a double qualification, is rapidly growing in favour with candidates for a registrable diploma. The wonder is that it has not sooner become the generally sought qualification, the honourable *prestige* of the College, and the equal strictness of the examinations alike being such as should approve it to students. Certain changes in the scheme of examination for licentiates are under consideration, but await the formal sanction of the whole board ere they come into force. Three examinations will have to be passed under the new rules. The college comprises three classes of members, viz., *Fellows*, *Members*, and *Licentiates*.

The Fellowship.—The Fellowship of the College is attainable only by election, and no one can be proposed who is not a member of at least four years' standing.

The Membership.—A person may become a member without holding a degree in medicine, or, indeed, any diploma. But every candidate who shall have commenced his professional studies after September, 1861, shall satisfy the Censors' Board that previous to such commencement he has obtained a degree in Arts from some university of the United Kingdom or of the Colonies, or from some other university specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a degree in Arts. The curriculum extends over five years.

The following additional regulations for the membership came into force on Jan. 30th, 1878 :—1. Any candidate who shall produce satisfactory evidence of having passed an examination on chemistry and materia medica, required for a degree in medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects, 2. Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a university in the United Kingdom, in India, or in a British colony, or who shall have obtained a qualification entitling him to practice medicine or surgery in the country where such qualification has been conferred, wherein the course of study and the examinations to be undergone previously to graduation shall have been adjudged by the Censors' Board to be satisfactory, shall be exempt (if the censors shall think fit) from all or any parts of the examinations hereinbefore described, except such as relate to the third or pass examination.

Graduates in medicine of any British university are admitted to an examination for the membership. Such graduates are exempt from some parts of the examination—*e.g.*, anatomy and physiology. Even graduates of accredited foreign universities have no difficulty in being admitted to examination. All persons who have been admitted before February 16, 1859, licentiates of the College, and also all extra-licentiates who are not engaged in the practice of pharmacy, may be proposed to be admitted a member of the College, Every candidate for the membership is expected to pass an examination, but there are certain cases, referred to under sections 15, 16, and 17 of the bye-laws of the College, in which the candidate is exempt from some portion of the examination.

The Licence.—The Licence of this College is a qualification to practise medicine, surgery, and midwifery, and is recognisable by the Poor-law Board as a qualification in surgery as well as in medicine, but unless a graduate in some university he is forbidden to use the title of doctor ; we regret, however, many do so. It was regarded at first as a diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially-appointed examiners, and is complete in the several departments. There are two examinations for the licence, the *first* of which may be passed after the termination of the second winter session, while the *second* examination cannot be passed until after four years of professional study. The fee for the College Licence is fifteen guineas, of which five are to be paid on admission to the first examination.

Every candidate will be required to produce satisfactory evidence of having completed the course of study in accordance with the bye-laws and regulations of the College, which may be obtained of the Registrar, and to pass the professional examinations conducted by the Examining Board.

Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a qualification which entitles him to practise medicine or surgery in the country where such qualification has been conferred, after a course of study and an examination equivalent to those required by the regulations of the College, shall, on production of satisfactory evidence as to age, moral character, and proficiency in vaccination, be admissible to the pass examination, and shall be exempt from re-examination on such subjects as shall in each case be considered by the Censors' Board as unnecessary.

Royal College of Surgeons of Englund,

This College has exercised much influence over the profession, for without the M.R.C.S. it is not easy to obtain any English surgical appointment. Its membership, although no longer essential, yet carries some weight in a parish appointment. For this reason most English students take this diploma, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College gives four diplomas—the membership, fellowship, a diploma in dental surgery, and one in midwifery, which last is, however, mostly confined to those who are already members.

The Membership.—This diploma gives no vote in the affairs of the College. It is only a licence to practise, and corresponds with the licentiateship of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the practice of medicine, although there are certain conditions on which he can claim exemption. He must also have passed the preliminary examination of the College, or one that is recognised by the College. There are now two professional examinations for the membership, the Primary and the Pass.

The Fellowship.—Members of long standing are often admitted to the fellowship by election. As, however, this grade is obtainable by examination, is of greater value, and needs no personal influence, men who have sufficient time and ability prefer the F.R.C.S. after examination.

For the Fellowship he must be a Member of the College of eight years' standing, and is admitted to examination on producing a certificate signed by three Fellows to the effect that he has been engaged in the Practice of Surgery for eight years, and is a fit and proper person to be admitted as a Fellow.

Few consulting surgeons in England are without the Fellowship, and in most of the London hospitals appointments are unattainable without it.

MEDICAL SCHOOLS OF LONDON.

THERE are in the metropolis eleven medical educational centres. Each of these comprises a fully appointed hospital, with medical school attached. The student, who is doubtful as to which he shall direct his steps, will be much puzzled how to decide on the one most likely to benefit him in the prosecution of his medical studies. In determining this point he should avail himself largely of the advice to be obtained from those conversant with the merits of the different institutions, and especially wilt he be wise to pay every heed to students senior to himself. Naturally every man so appealed to will declare his own *alma mater* to be *the* best school, but in spite of this, the partial information so obtained will be of great value, supplemented as it always should be by personal inspection of the institutions themselves. The country candidate will always find the most courteous readiness on the part of the officials at the various hospital schools, to lend him every assistance in ascertaining the advantages connected with each particular place; and before definitely selecting the hospital he will enter, the student should adopt the plan we have suggested. In many instances his choice will be guided by traditions and associations. It may be, father or brother has been at one or other place, and as a matter of course, the connection re-formed with it is maintained. This should be so. We write, however, more especially, for the guidance of those who are called upon to decide for themselves, and we repeat the suggestion we have made—hear all you can, and finally act on your own judgment and experience.

The London schools are the following:—Guy's, St. Bartholomew's, St. George's, King's College, the London, the Middlesex, St. Mary's, Charing Cross, the Westminster, University College, and St. Thomas's, and we shall notice them in alphabetical order.

The above are for men only. There is also a Medical College for Women, in full operation, in Henrietta Street, Brunswick Square. The clinical instruction is given in the wards of the Royal Free Hospital.

APPOINTMENTS, PRIZES, NEW SCALE OF FEES, &c.

ST. BARTHOLOMEW'S HOSPITAL. — *Appointments:* Four house-physicians and four house-surgeons are appointed annually without fee; each is provided with rooms and receives a salary of £25. A resident midwifery assistant and an ophthalmic house-surgeon are appointed every six months; they are provided with rooms, and receive a salary of £25 per year. The assistant chloroformist, salary £25 and rooms; in-patient clinical clerks; clerks and dressers to the assistant-physicians.

Scholarships, &c.—There are two open scholarships in science, value £130, tenable for one year; Jeaffreson exhibition, value £50, tenable for two years; preliminary scientific exhibition, value £50, tenable for one year; three junior scholarships, of £50, £30, and £20 respectively; Treasurer's prize for practical anatomy; Foster prize for practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize; Hichens prize; Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine.

Scale of Fees.—Fees for perpetual attendance on lectures and hospital practice, 132 guineas, payable in the following instalments:—First winter, 40 guineas; first summer, 46 guineas; second winter, 46 guineas; or a single payment of 125 guineas. Fee for general subjects for students of dental surgery:—First winter, 31½ guineas; first summer, 31½ guineas; or a single payment of 63 guineas.

CHARING CROSS HOSPITAL.—*Appointments:* Medical and surgical registrars, each with a salary of £40 a year; resident medical officer, assistant medical officer, resident surgical officer, assistant surgical officer, resident obstetrical officer, assistant demonstrator, pathological assistant, clinical clerks and dressers. The resident officers are provided with rooms and commons, and the assistant officers with commons, in the hospital.

Scholarships, &c.—Two entrance scholarships of £30 and £20 respectively, tenable for one year; the Llewellyn scholarship of £25, open to all matriculated students who have completed their second year; the Golding scholarship of £15, open to matriculated students who have completed their first year; the Pereira prize of £4; the Governor's clinical gold medal. Silver and bronze medals and certificates of honour are awarded to the most deserving candidates in the various classes.

Scale of Fees.—Composition fee for matriculated students, £81 7s., payable in instalments, or first year's fee, £38 17s.; second year's fees, £36 15s.; third year's fees, £10 10s. Composition fee for the course of dental surgery, £42 2s.

ST. GEORGE'S HOSPITAL.—*Appointments:* House-physicians and house-surgeons are elected half-yearly from among the perpetual pupils. They are entitled to hold their appointments for twelve months, and to board and reside in the hospital, free of all expense; assistant house-physician; assistant house-surgeon; obstetric assistant, with a yearly salary of £100, and board and residence in the hospital; pathological curator, with a salary of £50; microscopical pathologist, with a salary of £25; medical and surgical registrars, each with a salary of £50 per annum; assistant medical registrars; assistant surgical registrars; ophthalmic registrar; ophthalmic assistant; demonstrator of anatomy, with a salary of £50; senior assistant demonstrator, with a salary of £20.

Exhibitions, &c.—The Brown exhibitions, one of £100 per annum, tenable for two years, and open to perpetual pupils possessing a registerable diploma; and one of £40 per annum, tenable for three years, and open to students in their third year. The Brackenbury prizes; one each in medicine and surgery. The Clarke good conduct prize, the Thompson medal, the Brodie clinical prize in surgery, the Acland clinical prize in medicine, the Johnson memorial prize in anatomy, the Treasurer's prize, and three proficiency prizes of 10 guineas each.

Scale of Fees.—Competition fee for perpetual pupils, £125, or in the following instalments: first year £45, second year £45, third year £40. For attendance on the hospital practice and lectures required by the examining corporations, £45 for the first year, £45 for the second year, and £20 for each succeeding year. The latter scale of payment does not entitle the pupil to become house-physician or house-surgeon, or to compete for the Brown exhibitions. The fee for general subjects in dental surgery is £55, payable in two instalments, first year £30, second year £25.

GUY'S HOSPITAL.—*Appointments:* The house-surgeons and house-physicians, the obstetric residents, clinical assistants and dressers, are selected from the students, according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships, &c.— Open scholarship of 125 guineas, in classics, mathematics, and modern languages. Open scholarship, of 125 guineas, in chemistry, physics, botany, and zoology. Six scholarships, varying in value from £10 to £50 each, for general proficiency in medical study. The Joseph Hoare prizes; the Treasurer's gold medal in medicine; the Treasurer's gold medal in surgery; the Gurney

Hoare prize of £25, for clinical study; the Sand Cox scholarship of £15 per annum for three years, for physiology and physics; the Michael Harris prize of £10, for anatomy.

Scale of Fees.—For the entire course of lectures and hospital practice, 125 guineas if paid in one sum on entrance, or by two equal instalments of £66, payable at the commencement of the first winter, and of the following summer session; or payment may be made by instalments of £50, £50, and £37 10s,, payable at the beginning of the first, second, and third years respectively. Fee for the dental course, 63 guineas, or in two annual instalments of 40 guineas and 23 guineas.

KING'S COLLEGE HOSPITAL.— *Appointments:* One physician's assistant, two house-surgeons, and one physician-accoucheur's assistant, appointed every six months. They are supplied with board and residence in the hospital on payment of £30 each. Assistant house-physician, assistant house-surgeon, and assistant resident accoucheur, appointed every six months; in-patient clinical clerks and dressers; out-patient clerks and dressers; obstetric clerks, ophthalmic, dental, and aural assistants; post-mortem clerks; assistant demonstrators and prosectors of anatomy.

Scholarships, &c.—Three Warneford scholarships, each of the value of £25 per annum, two tenable for three years, and one tenable for two years; one Warneford scholarship of £25 per annum, tenable for two years, open to resident students; three junior scholarships of £20 each, tenable for one year, and open to students of the first year; one second year scholarship of £30 tenable for one year, and open to students of the second and third years; the senior scholarship of £40, tenable for two years, and open to students of the third and fourth years; Daniell scholarship of £20 per annum, tenable for two years, for work in the chemical laboratory; two Sambrooke registrarships, each of £50 per annum; one science exhibition of £100; two Warneford prizes of £25 and £15 respectively; Leathes prize; Todd medical clinical prize; Jelf medal; Tanner prize of £10 for obstetrics. Class prizes, each of the value of £3, are awarded annually in particular subjects.

Scale of Fees.—Payment for the entire course of hospital practice and college lectures may be made in one sum, viz., £125 on entrance, or by the following instalments:—£60 on entrance, £50 at the beginning of the second winter session, and £25 at the beginning of the third winter session. Fees for the dental course, £95 1s. 6d.

LONDON HOSPITAL.—*Appointments:* The resident and other hospital appointments are free to full students. The resident appointments consist of five house-physiciancies, four house-surgeoncies, and one accoucheurship; also two dresserships and two maternity assistantships.

Scholarships, &c.—Two entrance science scholarships, value £60 and £40, and two Buxton scholarships, value £30 and £20, will be offered for competition at the end of September to new students. Entries on or before September 20th. A scholarship, value £20, in human anatomy, to first year's students; a scholarship, value £25, in anatomy, physiology, and chemistry, to second year's students; a scholarship, value £20, in clinical medicine; a scholarship, value £20, in clinical surgery; a scholarship, value £20, in clinical obstetrics; the Duckworth Nelson prize, value £10 (biennial), in clinical medicine and surgery. Prizes, value £60, to dressers of out-patients, in minor surgery.

Scale of Fees.—Perpetual fee for lectures and hospital practice, and two years' practical anatomy, payable in three instalments of 40, 35, and 25 guineas, at the commencement of the 1st, 2nd, and 3rd years respectively, 100, or if in one payment, 90 guineas. Composition fee for students entering at or before the beginning of their second winter session, their first year having been spent elsewhere, payable in two instalments of 40 and 35 guineas, 75 guineas; or if in one payment, 70 guineas. Perpetual fee for lectures alone, 50 guineas; perpetual fee for hospital practice alone, 50 guineas; dental students (general hospital practice and lectures), 40 guineas; perpetual fee for dental practice, 10 guineas.

ST. MARY'S HOSPITAL.—*Appointments:* There are four resident medical officers, three of whom are appointed for twelve months, and one, the obstetric officer, for six months; all of them live, free of every expense, in the hospital. Two prosecutors, appointed annually; a demonstrator of anatomy, a medical tutor, and a resident registrar, each with a salary of £100 a year, appointed annually, and eligible for re-election. Clinical clerks and dressers.

Scholarships, &c.—Two scholarships in natural science, tenable for three years; an exhibition in natural science of £20, tenable for one year; a scholarship in anatomy of £20, tenable for one year; a scholarship in pathological anatomy of £40, tenable for one year. At the end of each session prizes ranging in value from £2 2s. to £4 4s. are given for proficiency in particular subjects.

Scale of Fees.—For unlimited attendance on lectures and hospital practice, £125 guineas if paid by instalments, or 119 guineas if paid in one sum. Fee for hospital practice and lectures required by the examining bodies, 107 guineas in instalments, or 101 guineas in one sum. Fee for dental students, 62½ guineas.

MIDDLESEX HOSPITAL.—*Appointments:* Two house-surgeons, three resident physician's assistants, resident obstetric physician's assistant. The above officers have residence and board in the hospital free of expense, but they pay on appointment fees varying according to circumstances from 10 to 30 guineas.

Scholarships, &c.—Two Broderip scholarships of £30 and £20 per annum respectively, tenable for two years, for medicine and surgery; two entrance scholarships of £25 and £20 per annum respectively, tenable for two years; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21; clinical prize of £10 10s.; class prizes in particular subjects.

Scale of Fees.—General fee for the entire course of hospital practice and lectures, £90, if paid in one sum on entrance or by instalments of £35, £35, and £20, payable at the commencement of the first, second, and third years respectively, and £10 for every additional year's attendance. Course of dental surgery, £42, payable in two instalments of £26 5s. and £15 15s.

ST. THOMAS'S HOSPITAL.—*Appsintments:* Two house-physicians, two house-surgeons, a resident accoucheur, two assistant-house physicians, two assistant house-surgeons, holding office for three or six months. The assistants are non-resident, but the other officers are provided with rooms and commons in the hospital free of expense. An ophthalmic clinical assistant, with salary of £50; surgical ward clerks, clinical clerks and dressers to in-patients and out-patients, obstetric clerks, two hospital registrars, each with a salary of £100; assistants in the dissecting-room, prosectors, pathological assistants, and assistants in the physiological laboratory.

Scholarships, &c.—Two entrance scholarships in natural science of £60 and £40 respectively; for first year's students, the William Tite scholarship of £30, and five college prizes ranging in value from £5 to £20; for second year's students, the Musgrove scholarship of £42, and five college prizes ranging in value from 5*l.* to 20*l.*; for third year's students, three college prizes of 20*l.*, 15*l.*, and 10*l.* respectively. In addition there are awarded the Cheselden Medal for surgery, the Mead medal for medicine, the Solly medal for reports of surgical cases, the Grainger testimonial prize of 20*l.* for a physiological essay, and the Treasurer's gold medal for general proficiency.

Scale of Fees.—For the entire course of hospital practice and lectures, 125*l.* paid on entrance; or 130*l.* in two payments, 70*l.* on entrance, and 60*l.* at the beginning of the next year; or by three instalments of 60*l.*, 50*l.*, and 30*l.*, at the beginning of the first, second, and third years respectively. The fee for the attendance on the *general* subjects required of students in dental surgery is for the two years 45*l.*, or by instalments; 50*l.* for the first year, and 10*l.* for the second year.

UNIVERSITY COLLEGE HOSPITAL.—*Appointments:* Six physicians' assistants, six house-surgeons, and four obstetric assistants, are selected annually by examination from among the senior students without additional fee. They reside in the hospital, paying only for their board, and have charge of the resident patients in the absence of the physicians and surgeons. The offices of physicians' clerks, surgeons' dressers, surgical ward clerks, and ophthalmic surgeons' assistants, are selected from among the pupils who are also students of the college, without additional fee.

Scholarships, Etc.—Three entrance exhibitions of 30*l.*, 20*l.*, and 10*l.* respectively, tenable for two years; Atkinson-Morley surgical scholarship, of 45*l.* a year, tenable for three years; Atchison scholarship, value about 55*l.*, tenable for two years; Sharpey physiological scholarship, value about 70*l.* a year, tenable for three years; Filliter exhibition for proficiency in pathological anatomy, value 30*l.*; Dr. Fellowes'

clinical medal ; the Liston gold medal ; Alexander Bruce gold medal ; Cluff memorial prize ; class medals, &c. ; gold and silver medals, or other prizes, as well as certificates of honour, are awarded, after competitive examinations in particular branches of study. Prizes to the value of 10*l.* will be given in the class of hygiene.

Scale of Fees.—125 guineas, if paid in one sum at the commencement of the course, or 130 guineas if paid by instalments, as follows : first year 60 guineas, second year 50 guineas, third year 20 guineas. Hospital practice and clinical instruction, perpetual, 31*l.* 15*s.* ; one year, 15*l.* 15*s.* ; six months, 10*l.* 10*s.* Practical pharmacy, three months, 5*l.* 5*s.*

WESTMINSTER HOSPITAL. — *Appointments* : There are numerous dresserships and clerkships : the posts of medical and surgical registrar, each with 40*l.* a year, and of house-physician, house-surgeon, resident obstetric assistant, assistant house-surgeon, physician's assistant, surgeon's assistant, ophthalmic assistant, and assistant in the skin department.

Scholarships, Etc.—Entrance scholarships next October.—The Fence, 50*l.* a year for two years, and two others value 50*l.* and 20*l.* Subjects—Latin, Mathematics, French or German, and Chemistry and Natural Philosophy. The Latin books the same as the June examination of the University of London matriculation—Ovid : Epistola ex Ponto. Books II. There are also—an exhibition, value 10*l.* 10*s.*, for first year's men ; a scholarship in anatomy and physiology, value 21*l.*, for second year's men ; prizes for clinical medicine and surgery of 5*l.* each ; the Frederic Bird medal and prize, value 15*l.* ; the Chadwick prize for proficiency, value 21*l.*

Scale of Fees.—In one payment, 92*l.* 10*s.* ; in two payments of 49*l.* each, payable on entrance and at commencements of second year respectively ; by payments distributed over five sessions, amounting to 107*l.* 2*s.* There are no extras, except parts for dissection. Fees for shorter periods or for single courses, may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 45*l.*

SPECIAL SCHOOLS.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

The winter session of 1880-81 opens on the 1st October. The fee for the ordinary curriculum of non-clinical lectures is £80, if paid in one sum, or if paid in instalments £40 for the first year, £30 for the second, and £15 for the third. The courses of lectures included in this fee are as follows : —Two courses each of anatomy, practical anatomy, physiology, and practice of medicine, and one course each of botany, chemistry, practical chemistry, materia medica, surgery, pathology, midwifery, diseases of women and forensic medicine. Certain classes are held annually, others bi-annually. The fee of £90 entitles a student to attend, in addition to the classes enumerated above, one course each of practical physiology, zoology, ophthalmic surgery, mental pathology, and hygiene. The London School of Medicine for Women is now recognised by the King and Queen's College of Physicians, Ireland, and by the University of London. Students of the school can therefore proceed to the examination for the licence to practise medicine of the college, and for the degrees of M.D. and M.S. of the university. Hospital instruction is obtained at the Royal Free Hospital, some ten minutes walk from the School ; the fee for which, including annual courses of clinical medicine and clinical surgery, is £20 for the first year, and £15 for each subsequent year. Clinical clerks, surgical dressers, are selected from among the senior students without further fee. Two entrance scholarships, value respectively £30 and £30 per annum, for three years, will be competed for at the school on the 24th and 25th September.

SCHOOL OF ANATOMY AND PHYSIOLOGY.

This is established for private tuition, and is situate close to University College, at 16 Woburn Place, its principal being Mr. Thomas Cooke, F.R.C.S., senior assistant surgeon to the Westminster hospital, assisted by demonstrators. The whole of the anatomy (on the dissected body), of physiology (with microscopical preparations and such experiments as the law permits) and operative surgery (on the dead body), are gone through carefully every three months. Fees : Three months, three guineas ; six months, four guineas : for the higher examinations, with *special* supplementary class five guineas. There is a well-appointed dissecting room near the school.

LONDON SCHOOL OF DENTAL SURGERY.

This institution is situated in Leicester Square. The meetings of the Odontological Society are also held here. In winter, lectures are delivered on mechanical dentistry by Dr. Walker, on Wednesdays at 7 p.m. ; on metallurgy in dentistry, by Dr. Louis, on Tuesdays and Fridays, at 12 o'clock, during October and November. In summer Mr. A. Colman lectures on dental surgery and pathology, and Mr. C. S. Tomes on dental anatomy and physiology. General fee for special lectures required for the curriculum, £15 15*s.* The Saunders scholarship of £20 per annum, and prizes, are open for competition. In connection with the above is the

DENTAL HOSPITAL OF LONDON.—Surgeons : Messrs. Fox, Medwin, Gregson, Coleman, Moon, and Hill. Assistant Surgeons : Messrs. Hepburn, F. Canton, Gibbings, Woodhouse, Hutchinson, and Bartlett. Dental House Surgeon : Mr. Bradshaw. Assistant Dental House Surgeon : Mr. Rees Price. Fees for two years' hospital practice, £15 15*s.* Fees for lectures and practice, £31 10*s.*

NATIONAL DENTAL COLLEGE.

This is a more modern institution than the one in Leicester Square, having been open about four years. In connection with it is the National Dental Hospital, situate in Great Portland Street, which was established in 1861. The teaching at this school is recognised by the Royal College of Surgeons for the dental diploma, and lectures and demonstrations are given similar to those at the other dental school. The following are the lecturers, with their subjects :—Dental anatomy and physiology : Mr. Thomas Gaddes. Dental surgery and pathology : Mr. Oakley Coles. Dental mechanics : Mr. G. Williams. Dental metallurgy : Mr. Alfred Tribe. Supplemental lectures.—Operative dental surgery : Dr. Thompson. Elements of histology : Mr. Thomas Gaddes. Demonstrations on dental mechanics ; Mr. Harry Rose. Deformities of the mouth : Mr. Oakley Coles. The session commences on October 4th. Fees.—General fee for special lectures required by the curriculum, £12 12*s.* Fee for the two years' hospital practice required by the curriculum, £12 12*s.* Total fee for the special lectures and hospital practice required by the curriculum, £25 4*s.*

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

Lectures are delivered on Monday, Tuesday, and Wednesday mornings at 9 o'clock. The course consists of sixty lectures. Two courses are given annually, the first commencing in October, and the second course in March, 1881. The subjects of these lectures are—(1) Physics in relation to chemistry and pharmacy. (2) Inorganic chemistry. (3) Organic chemistry, botany, and materia medica. These lectures are delivered on Thursday, Friday, and Saturday mornings at 9 o'clock. The laboratories are open from ten o'clock in the morning until five in the afternoon daily, except on Saturdays, when they are closed at two o'clock. Fees for ten months, according to hours of attendance, twelve to twenty-five guineas ; for shorter terms in proportion. Each student is expected to attend every lecture of the course for which he has entered, or to state the cause of absence to the professor or to an assistant.

SOUTH LONDON SCHOOL OF PHARMACY.

This school, which has accommodation for 120 students, is situated at Kennington Cross, and is decidedly the most popular institution for the study of practical pharmacy and chemistry in London. Instruction is also given in analytical chemistry for the purpose of qualifying gentlemen in search of appointments under the Public Health and Adulteration of Food Acts, by the principal, Dr. Muter. Lectures are delivered daily in the laboratory, and each student is required to practically illustrate that he grasps the subject taught as the lecturer proceeds. The percentage of pupils passing at the examination is exceptionally high from this school. The winter session commences a fortnight earlier than the medical schools.

SCHOOL OF HOMŒOPATHY.

Homœopathy has now a recognised teaching school for students, which is situate in Great Ormond Street, where lectures and instructions according to homœopathic principles are given by duly qualified members of the medical profession, and where students who believe in the *similia similibus curantur* theory can be taught according to their bent. The winter session at this school opens on October 1st.

NOTE.—*Where fuller information is required by the reader than that contained in the foregoing notes, it will generally be found on reference to our advertising columns, where also will be found the names of the staffs, lecturers, etc.*

HOURS OF THE INTRODUCTORY LECTURES

To be delivered at the different Metropolitan Schools.

St. Bartholomew's Hospital : None. Session commences Oct. 1st.
Charing-Cross Hospital : None. Session commences Oct 1st.
St. George's Hospital : Dr. Cavafy, Oct. 1st, at 4 p.m.
Guy's Hospital : None. Session commences Oct 1st.
King's College Hospital : Prof. G. Johnson, F.R.S., Oct. 1st, at 4 p.m.
London Hospital : None. Session commences Oct. 1st.
St. Mary's Hospital : Mr. Walter Pye, 3 p.m.
Middlesex Hospital : None. Session commences Oct. 4th.
St. Thomas's Hospital : Dr. Ord, Oct. 1st, at 3 p.m.
University College : Prof. Burdon Sanderson, F.R.S., Oct 4th, at 8 p.m.
Westminster Hospital : Dr. Dunkin, Oct 1st, at 3 p.m.

THE PRINCIPAL METROPOLITAN HOSPITALS TO WHICH NO MEDICAL SCHOOL IS ATTACHED.

Open to Students from the Larger Hospitals.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and important hospital at the East End, containing 164 beds. Consulting physicians: Drs. T. B. Peacock, J. Risdon Bennett, E. Lloyd Birkett, J. Andrew. Consulting surgeon: Mr. Erichsen, F.R.S. Physicians: Drs. S. H. Ward, J. C. Thorowgood, Shepherd, Eustace Smith. Assistant physicians: J. B. Berkhart, S. W. Berkhart, Fothergill, Heron, West, V. D. Harris, and J. A. Ormerod.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—This is the largest institution for the treatment of affections of the chest in the United Kingdom, and contains 192 beds. Consulting physicians: Drs. C. J. B. Williams, W. H. Walshe, and R. Quain. Consulting surgeon: Prof. John Marshall, F.R.S. Physicians: Drs. J. E. Pollock, E. S. Thomson, C. T. Williams, R. D. Powell, J. Tatham, R. Thompson, and J. Fowler. Assistant physicians: Drs. Burney Yeo, F. Roberts, T. H. Green, and J. M. Bruce. Dental surgeon: Mr. C. J. Noble. Resident medical officer: Mr. F. J. Hicks. Secretary: H. Dobbin. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital. Terms, £3 3s. for three months; perpetual, £5 5s.

HOSPITAL FOR DISEASES OF THE THROAT AND CHEST, Golden Square, W.; contains 21 beds, outposts, Newington-butts, Walworth, and St. John's Gardens, Notting Hill.—Physicians: Drs. Morell Mackenzie, Robert H. Semple, Prosser James, W. McNeill Whistler, and F. Semon. Surgeons: Dr. E. Woakes and Mr. W. R. H. Stewart. The practice of the hospital is open to students on payment; fee for three months' course three guineas; for six months five guineas; perpetual course seven guineas. Laryngoscopic demonstrations are given daily at half-past two.

CENTRAL LONDON THROAT HOSPITAL, Gray's-Inn Road.—25 beds. The staff consists of Mr. S. Jones, consulting surgeon, and Messrs. Lennox Browne and Llewelyn Thomas, surgeons. Assistant surgeons, Messrs. G. R. Steil, F. G. Hamilton, and A. Orwin. Six clinical assistants, being either qualified practitioners or students of three years' standing, are elected to assist the surgeons. Fees for three months' attendance two guineas; six months three guineas.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—This hospital treats above 6,000 out-patients annually, and makes up 26 beds. A new wing, of which the foundation stone was laid last year by Princess Louise, will raise the number of beds to over 60. Consulting physicians: Drs. Herbert Davies and Horace Dobell. Physicians: Drs. G. Goddard Rogers, P. J. Hensley, Gilbert Smith, and D. W. Finlay. Assistant Physicians: Drs. W. Murrel, H. S. Gabbett, and W. H. White. Consulting surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. W. Walsham. House hhysician: Mr. F. M. Pope.

EAST LONDON HOSPITAL FOR CHILDREN.—Physicians: Drs. Eustace Smith, and Horatio B. Donkin. Assistant physicians: Drs. Warner and Croker. Surgeons: Messrs. A. Cæsar, H. A. Reeves. Assistant surgeon: Mr. R. W. Parker. House surgeon: T. E. Hayward. Secretary: Mr. Ashton Warner.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen's Square, W.C., and Cromwell House, Highgate.—Physicians: Drs. Dickenson, Gee, and W. B. Cheadle. Assistant physicians: Drs. R. J. Lee, C. Sturges, Thomas Barlow, D. B. Lees, and Robert Bridges. Surgeons: Mr. T. Smith, Mr. F. Howard Marsh, Mr. Edward Owen, and Mr. J. H. Morgan. Surgeon-dentist: Mr. A. Cartwright. Fee for three months' attendance, £3 3s., perpetual, £5 5s. Secretary: Mr. S. Whitford. There are now 104 beds in the hospital, Great Ormond Street, and 52 beds in the country branch; total, 156. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London, on conditions which may be ascertained of the Secretary.

THE HOSPITAL FOR WOMEN, Soho Square, W.—Physicians: Protheroe Smith, Heywood Smith, C. H. Carter. Surgeon: H. A. Reeves. Assistant physicians: R. T. Smith, E. Holland, Mansell Moullin. House physician: Mr. Bottrell. Chloroformist: T. Bird. The hospital contains 61 beds. Clinical instruction is regularly given in the wards, and in the out-patient room daily at 10. Clinical clerks and assistants are appointed from time to time, application to be made to the physicians. Students to be received after the third year.

BRITISH LYING-IN HOSPITAL, Endell Street, St. Giles's, W.C.—25 beds. Consulting physician: Dr. Priestley. Consulting surgeon, T. Spencer Wells. Physicians; Drs. Heywood Smith, Arthur Edis, and S. Fancourt Barnes. This institution receives women only as midwifery pupils. The fee for the course of three months is £10 10s. Pupils who prove themselves competent receive a certificate signed by the physicians, enabling them to practise midwifery.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street.—52 beds. Physicians: C. H. F. Routh, W. R. Rogers, W. H. Day, Wynn Williams, P. Boulton, F. H. Champneys, and Prickett. Surgeons: G. C. Bantock, J. K. Thornton, A. H. G. Doran, and W. A. Meredith.

ROYAL LONDON OPHTHALMIC HOSPITAL, Bloomfield Street, Moorfields, is the largest of its class in the metropolis, and contains 100 beds. Consulting physician: Dr. F. J. Farre. Consulting surgeons: Messrs. J. Dixon, G. Critchett, W. Bowman, F.R.S., and J. Hutchinson. Surgeons: Messrs. Wordsworth, Streatfield, Hulke, Lawson, Couper, and Lyell. Assistant surgeons: W. Tay, J. E. Adams, J. Tweedy. House surgeon: Mr. Gunn. Number of patients annually, about 20,000.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, Charing Cross.—The hospital contains 50 beds, and is attached to the practice of Charing Cross Hospital. Fees for six months, £3 3s., perpetual, £5 5s. Students of the hospital are eligible for the post of house surgeon.

LONDON FEVER HOSPITAL, Islington.—260 beds. Consulting physician: Dr. Tweedie. Physicians: Drs. Broadbent and Cayley. Assistant physician: Dr. Mahomed. Consulting surgeon: Mr. W. S. Savory. Resident medical officer: Mr. Tonge-Smith.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, 54 Berners Street, Oxford Street.—Surgeons: Walter J. Coulson, W. F. Teevan. Assistant surgeon: Dr. F. R. Heycock. Resident medical officer: Dr. Macnaughton. Medical men and students are admitted to the practice of the hospital gratis. It contains 16 beds, and 154 in-patients were treated during the past year. The number of out-patients was 14,000.

GREAT NORTHERN HOSPITAL, Caledonian Road.—Physicians: Drs. Cholmeley, Cooke, Bridges, and Burnett. Obstetric physician: Dr. Gustavus C. P. Murray. Consulting surgeons: Mr. F. Le Gros Clark, F.R.S. Surgeons: Messrs. Gay, W. Adams, W. Spencer Watson, W. H. Cripps, and J. Macready. Ophthalmic surgeon: Dr. R. W. Lyell. Aural surgeon: Mr. A. E. Cumberbatch. Dental surgeon: Mr. C. J. Fox. Chloroformist: Mr. Eastes. House surgeon: Mr. A. Wharry.

WEST LONDON HOSPITAL.—A well appointed hospital at the western extremity of the metropolis in the Hammersmith Road, containing 60 beds. Consulting physician: Dr. Maudsley. Consulting physician-accoucheur: Dr. W. O. Priestley. Consulting surgeons: Messrs. S. A. Lane and William Bird. Physicians: Drs. Goddard, Rogers, and Thorowgood. Physician for diseases of women: Dr. Wiltshire. Surgeons: Messrs. W. F. Teevan and Alfred Cooper. Ophthalmic surgeon: Mr. B. J. Vernon. Assistant physicians: Drs. Fish, Fothergill, and D. W. C. Hood. Assistant surgeons: Messrs. Keetley, Morgan, and Edwards. Surgeon-dentist: Mr. Smale. Resident medical officers, two house surgeons, and an apothecary. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information by application to Mr. Gilbert, at the hospital,

BETHLEM HOSPITAL.—This hospital is open for the admission of two resident medical students, who have recently obtained their diplomas to practise medicine and surgery, for the acquisition of knowledge regarding the insane. The next election takes plaee in October, at Bridewell Hospital, and the elected candidates will be expected to commence residence on the 1st of November.

ROYAL FREE HOSPITAL, Gray's Inn Road.—This hospital contains 150 beds. Of the smaller metropolitan hospitals few offer more extensive field for students in medicine and surgery. An arrangement has been made by which medical students from the School of Medicine for women are enabled to attend their hospital courses at this institution. Physicians: Drs. Hassall and Cockle. Surgeons: Messrs. F. J. Gant and W. Rose. Secretary: Mr. J. S. Blyth, from whom full particulars of the dresserships and clerkships may be obtained. Assistant surgeon: Mr. W. H. Cripps. House surgeon: Mr. R. Atkinson.

ROYAL ORTHOPÆDIC HOSPITAL.—Pupils are admitted to witness the practice of this hospital on the following terms. Six months, £3 3s.; twelve months, £5 5s.; perpetual, £10 10s. Surgeons: Messrs. B. E. Broadhurst, H. A. Reeves, C. Reid, and W. E. Balkwill. House surgeon: Mr. H. F. Baker. Operations on Mondays, at 2 p.m.

THE TEMPERANCE HOSPITAL.—The character of this institution is fully described by its title, and the non-alcoholic treatment is carried out in its entirety by an efficient staff. It is situated close to the University College in Gower Street.

SEAMEN'S HOSPITAL (late *Dreadnought*) Greenwich.—300 beds. For the reception of seamen of all nations who are received at all hours. Apartments are provided in the house of the surgeon for students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad.

ENGLISH PROVINCIAL MEDICAL SCHOOLS.

BIRMINGHAM: QUEEN'S COLLEGE.—Students are admitted—(1)

as matriculated students who enter for their entire medical education; (2) as occasional students for one or more courses of lectures; (3) as junior students, to prepare for the preliminary examinations of the licensing boards.

Scholarships, Prizes, &c.—The Sands Cox prize, value £20. Open to students who have completed their curriculum. Subjects:—Medicine, Surgery, and Midwifery. Two Ingleby scholarships for obstetric medicine and surgery and diseases of women. The Warden's prize, value £5 5s., for first year's students, for general proficiency. The Percy prize, value £5 5s., for German.

Fees.—College fee for all lectures amount to 60 guineas, payable by two equal instalments.

Hospital practice is obtained at the General and Queen's Hospitals, which have been amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board by whose order all schedules are signed and all examinations conducted. The hospitals have a total of upwards of 400 beds, and the staff attached is of a very high order.

All students will be required to attend six months alternately at each hospital, as directed by the Clinical Board, excepting students who enter the hospital for six months only.

Clinical Prizes.—The following prizes are given annually: Senior medical prize for third and fourth year's students, first prize, £5 5s.; second prize £3 3s. Senior surgical prize, for third and fourth year's students, first prize, £5 5s.; second prize, £3 3s. Junior medical prize, for second year's students, first prize, £3 3s. second prize, £2 2s. Junior surgical prize for second year's students, first prize, £3 3s., second prize, £2 2s. Midwifery prize £4. Medals and certificates are awarded in each class. The examinations for all the appointments and prizes are conducted by the Clinical Board, and are open for competition to all students registered by the Clinical Board.

Fees for attendance for four years on the medical and surgical practice, and on the clinical lectures at both hospitals, £42.

Bristol School of Medicine (University College).—Attached to this school, where there is ample provision for education and practice, are two well-appointed hospitals, the Royal Infirmary containing 264 beds, and the General Hospital, with 154 beds. Competitive examinations are held amongst students of the first, second, and third years respectively, and prizes of money, instruments, and books are awarded annually. The certificates of this school are accepted by all the examining boards. Medical and surgical hospital practice and clinical lectures are attended at the Royal Infirmary or at the General Hospital, at which institutions additional prizes are annually offered for competition amongst the students. The existing medical school forms a department of the College of Science and Literature.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in the medical school to first, second, and third year's students, and also in practical anatomy. At the Royal Infirmary—Suple's medical prize, a gold medal and £7 7s.; Suple's surgical prize, as the medical; Clark prize (interest of £100) for third year's student; pathological prize, £3 3s. At the General Hospital: Martyn memorial scholarship £20; Clarke scholarship (surgical) £15. Sander's scholarship (interest of £500), medicine and surgery; Lady Haberfield's prize (£1,000), for general proficiency.

Clinical lectures are given at both institutions, three and four times a week.

Fees.—School fees for unlimited attendance on all courses of lectures except comparative anatomy, 60 guineas.

Leeds School of Medicine.—Clinical lectures are given by the physicians and surgeons attached to the General Infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the Infirmary by the surgeons in each department, where also are obtainable six clinical clerkships and eight dresserships. Besides the Infirmary there is a large Dispensary and a fever hospital, both of which are open to students of the school. Students at this school have excellent opportunities of acquiring a thorough insight of pyschological medicine, as the renowned West Riding Lunatic Asylum is in connection, and Dr. Major lectures on mental diseases. The systematic lectures are given at the school, and the clinical lectures at the asylum, which now accommodates 1,500 patients.

There is the Hardwicke scholarship in clinical medicine, value £10, the Thorp, in forensic medicine, value 10*l.*; three surgeons' clinical prizes, of £8, £5, and £3 respectively. Silver and bronze medals, books, and certificates of honour are awarded for proficiency in particular subjects.

The composition fee for attendance upon all the required courses of school lectures is £50 8s., to be paid on entrance; or £26 5s. on entrance, and a second sum of £26 5s. twelve months afterwards.

At the General Infirmary the perpetual fee for medical practice and clinical lectures is £26 5s. The same amount is charged for the perpetual attendance on the surgical practice and clinical lectures. These fees are not included in the composition fees for lectures, and are payable separately.

Liverpool Royal Infirmary School of Medicine.—The infirmary attached to this school, which contains 300 beds, with 40 special wards for the treatment of diseases of women, is perhaps second to none in England in its general appointments, and the facilities it offers to students for gaining practical knowledge.

A payment of 50 guineas on entrance, or in two equal instalments (one half on entrance, and the remainder within twelve months), entitles the student to attendance on all the necessary lectures and demonstrations. The Royal Infirmary contains nearly 300 beds. There are special wards for the treatment of uterine and other diseases of women. During the year 1878 2,700 patients were admitted into the infirmary; the number of out-patients was 5,300. The Lock Hospital adjoining the infirmary contains 60 beds; during the past year 598 males and females were admitted as in-patients, the daily average number in the house being 41.

Two house physicianships and three house surgeonships, tenable for six months, and open to pupils of the school who have obtained a legal qualification; clinical clerks and dressers; post-mortem clerks.

Two Roger Lyon Jones scholarships, each of £21, for two years, one awarded as an entrance scholarship, and the other being open to students who have completed their second year; the Torr gold medal for anatomy and physiology; the Bligh gold medal for anatomy and physiology. School medals and certificates of honour are awarded for proficiency in certain groups of subjects.

The fee for a perpetual ticket for hospital practice is £33 12s., and may be paid in two equal instalments (one-half on entrance, and the remainder within twelve months).

Manchester: Owens College School of Medicine.—This school, as most of our readers are aware, has resulted from the amalgamation of the Manchester Royal Infirmary School of Medicine with the Owens College, and occupies in the provinces a somewhat similar position to that of University College and Hospital in London. It has a faculty of science as well as of medicine, with departments of law and arts. Since the amalgamation a new medical school has been built on the most improved principles, at the western extremity of the college estate. On the ground floor are two large lecture theatres, a library, and a museum. Over the lecture theatre is a dissecting-room, and over the library a physiological laboratory. The course of instruction afforded to students is thoroughly complete. Three of the most important chairs—those of anatomy, physiology, and chemistry—are held by professors who entirely devote their time to the work of instruction. Students wishing to engage in physiological or pathological researches will find opportunities for study in the complete and well-furnished physiological laboratory. Two valuable physiological scholarships are placed for competition in this branch as an incentive to original research.

Appointments.—Resident medical officer £250 per annum; resident medical officer at Cheadle, £150; resident medical officer at Monsall, £200; resident surgical officer, £150; eight house-surgeons, six months each; four house physicians for six months each; a registrar; a pathological registrar, 100*l.* each.

Scholarships, Prizes, &c.—Turner scholarship 25*l.*, for third year's men; Platt physiological scholarship, two, 50*l.* each, five years; one annually for physiology. Platt exhibitions: Details of these will be forwarded early in the session on application. Dumville surgical prize, 20*l.*; examination takes place April 29 and 30, 1881. Prizes of books, instruments, &c., varying from 5*l.* 5s. to 3*l.* 3*s.*, for third, second, and first year's students. Entrance for scholarships. Dauntesey medical scholarship: candidates not to be over 25 years of age; may be registered, but must not have studied at any medical school; value about 100*l.*, for one year; successful candidates must at once enter on full medical course in the Owens College. Examination commences October 1st, 1880. Subjects—General and comparative anatomy, physiological botany, chemistry, including practical work, and either mathematics or Latin. Gilchrist scholarships:—Three of 50*l.* for three years. One is annually awarded to candidates standing highest at matriculation of London University in June (provided he be in the honours division); failing such, two of 25*l.* to the two candidates standing highest in the first division; candidates must be between 16 and 20 years of age. There are also grammar school scholarships.

Fees.—Composition fee 63*l.*, or two sums of 31*l.* 10s. each. Hospital practice: composition fee 42*l.*, or two instalments of 22*l.* each. Further information may be obtained of Professor Gamgee, Dean of the School, or of the Registrar, M. J. Holme Nicholson, Owens College, Manchester.

Newcastle-on-Tyne College of Medicine.—This school is a department of the University of Durham, and contains ample provision for acquiring a sound education and practical experience at the bedside. It is smaller than some of the provincial schools, but with some parents and students this would be considered an advantage.

Hospital practice is obtained at the Newcastle Infirmary, which has 250 beds, and in which the required clinical lectures are delivered.

Fuller information of this college will be found under the heading University of Durham.

SHEFFIELD SCHOOL OF MEDICINE.—Students at this college obtain excellent instruction in medical and surgical practice at the General Infirmary, which contains 180 beds, and is provided with a museum and pathological and post-mortem theatres. The fees for perpetual attendance are 15*l.* 15s. for medical, and 21*l.* for surgical practice; for twelve months' medical and surgical practice, each 10*l.* 10s.; and for six months 6*l.* 6s. each. There is also the Sheffield Hospital and Dispensary, containing 104 beds, and is recognised by the College of Surgeons and the Hospital for Diseases of Women, to which students are admitted. The perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, 42*l.* Prizes to the value of 30*l.* and certificates of honour are given annually. Some of the lecturers, and other local members of the profession, receive house pupils, which will be found far preferable to life in ordinary lodgings.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—This institution is one of the largest in the English provinces, and contains 200 beds. It has no school proper, although it contains accommodation for resident pupils, and clinical lectures are delivered daily by members of the staff. These, together with the practice obtained here, which is of a very varied and valuable character, is recognised by all the examining boards. Inclusive fees—perpetual, 25 guineas; one year, 10 guineas; six months, 7 guineas; three months, 4 guineas. Students can enter to the medical or surgical practice separately on payment of half the above fees.

NOTE.—*Our advertising columns, of which an index will be found at the end of the editorial matter, will supply further information, with the names of staff, &c., attached to the foregoing schools.*

IRISH QUALIFICATIONS TO PRACTISE.

THE Medical Licensing Bodies of Ireland are five in number, and, as a rule, medical students gravitate into one or other of three classes. *a.* Those who enter Trinity College, and take a full graduation in Arts, in addition to their professional degrees. *b.* Those who take the M.D. of the Queen's University, having put in a part or the whole of their term of study in the Queen's Colleges at Cork, Galway, and Belfast. *c.* Those who take the Licenses of the College of Surgeons with that of the College of Physicians or Apothecaries' Hall. A fourth minor class is constituted by the those who pursue their studies in Ireland, but who, either to escape the extended course of study required in Ireland, or to save the consequent fees, or because they cannot pass the Irish examination, migrate to Edinburgh or Glasgow for their licenses. Almost all these emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, almost without exception, in Dublin.

The Irish licensing bodies are as follows :—

THE UNIVERSITY OF DUBLIN.—It grants the degrees of M.B. and B.Ch. to students who have obtained their Arts degree, and the higher degrees of M.D. and M.Ch. to those who have held, for at least three years, the grade of M.B and B.Ch. It does not grant degrees to ungraduated students; consequently, its licenses hold the highest rank as social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degree of Bachelor in Medicine and Bachelor in Surgery in the University of Dublin is approximately as follows :—Lectures, £59 1s.; Hospitals, £44 2s.; Degree Fees, £26 = £129 3s.; Private Tuition, say £20; Total, £149 3s.

The expense of the degree of Bachelor in Arts, amounting altogether to £83 4s., should be added to the foregoing, making the total cost £212 7s.

The University also grants a midwifery degree (M.A.O.) to its own medical graduates, at an additional fee of £5.

The regulations for the University degrees will be found at page 249.

THE COLLEGE OF SURGEONS' license, or L.R.C.S.I., is universally sought for by those students who do not resort to a University. Its course of study extends over three years, and it holds the only extra-university preliminary examination, save that of the Apothecaries' Hall. It grants the higher qualification of Fellow or F.R.C.S.I., to those who are specially qualified and specially examined for that diploma, and it also confers a midwifery diploma on examination by a special Court of Examiners.

THE COLLEGE OF PHYSICIANS grants its license, L.K.Q.C.P.—the usual medical qualification of the Irish student—which is almost always taken by the young surgeon immediately after his passing at the College of Surgeons, and for it the same curriculum of study is sufficient. The College has recently established a higher qualification of "Member," for which there is a special examination, and there is also the still higher grade of Fellow of the College, to which admission is by ballot without examination or curriculum.

The cost of obtaining the L.R.C.S.I. with the L.K.Q.C.P.I., and the license in midwifery, is nearly as possible as follows :—

Lectures, &c.	£65	0	0
Hospital	36	0	0
Diploma fees L.R.C.S. ...	26	0	0
Diploma fees L.K.Q.C.P. ...	15	15	0
Diploma fees Lic. Mid. ...	3	3	0
	£145	18	0

The lecture fees may be reduced to £57 by making a cash composition for them; but, as a certificate of study in vaccination is now required, and a course of attendance at a midwifery hospital is requisite for the midwifery diploma, the total expense of the Dublin double diploma may be set down at £150.

The regulations of these bodies will be found at page 250.

THE QUEEN'S UNIVERSITY grants the degree of M.D. only, but grants it to any student who puts in a couple of courses in a Queen's College. The examination for the degree holds a high standard, but the degree, as it is obtainable with only a nominal Arts education and academic residence, does not occupy the same grade as the M.D. Dub. Univ. It, however, costs only £5, and is granted upon a much less extended curriculum than that required by the Dublin Colleges, and it is, therefore, in demand. Moreover, the lecture fees in the Queen's Colleges are generally not more than one-third of those charged by the Dublin lecturers, and, therefore, the cost of obtaining the M.D. Q.U.I. is very low by comparison. The following is a near estimate :—M.D. and M.Ch. (all lectures being taken in the provincial colleges.)—£62 9s.; ditto (two years' lectures and hospital taken in Dublin) say, £85.

THE APOTHECARIES' COMPANY grants a registrable license (L.A.H.), which is accepted by the Local Government Board as a medical qualification, and which, in addition, entitles the holder to keep open shop and sell drugs in Ireland. It only costs 10s., and it is taken in lieu of the License of the College of Physicians by a few Students to whom the money cost of their qualification is vitally important, or who intend to open an establishment in some of the provincial towns for the dispensing of medicines. Since the establishment of the Irish Pharmaceutical Society, which is empowered to grant pharmacy licenses, the demand for the L.A.H. has been nominal. The cost of the L.A.H., with the necessary curriculum of study, is about £59; that of the L.R.C.S.I., combined with the L.A.H., and a License in Midwifery, is about £130.

The regulations of the "Hall" will be found at page 251.

OFFICIAL REGULATIONS OF LICENSING BODIES IN IRELAND.

UNIVERSITY OF DUBLIN.

(For Names of Professors and Examiners see Advertisement in our pages).

REGULATIONS OF THE SCHOOL OF PHYSIC.

Matriculation.—Every student must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable; but he need not attend any of the Arts courses unless he desire to obtain a licence or degree in medicine or surgery. No student can matriculate unless he has passed the Entrance Examination in Trinity College, in the Royal College of Surgeons of Ireland, or some other examination recognised by the General Medical Council. No student can be admitted for the Winter Courses after the 25th November.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine—Candidates must be graduates in Arts, and may obtain the degrees at the same commencement as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures :—

Winter Courses.—Anatomy; physiology; practical anatomy; surgery; chemistry; practice of medicine; midwifery; heat, electricity, and magnetism.

Summer Courses.—Botany; materia medica and pharmacy; practical histology; medical jurisprudence; comparative anatomy. Hospital attendance on a medico-chirurgical hospital during three courses of nine months each, with clinical lectures, including actual attendance on fever; six months' practical midwifery; six months' dissections; and three months' laboratory instruction in chemistry are required. The Courses may be attended at any recognised medical school. The fee for the *Liceat ad Examinandum* is £5. The fee for the degree of M.B. is £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B., or qualified to take that degree, for three years. He must also read a thesis before the Regius Professor of Physic. Total fee for this degree, £13.

Bachelor in Surgery must be a B.A., have spent four years in the study of surgery and anatomy, and passed the M.B. examination. The curriculum comprises the following, in addition to the course for the M.B. :—

Theoretical and operative surgery ...	One course.
Dissection	Two courses.
Ophthalmic surgery	One course.

Candidates are required to perform operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5. Fee for the degree of Bachelor in Surgery, £5.

Master in Surgery must be a B.Ch. of three years' standing, and must read a thesis. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science (a Degree lately founded by order of the Board of T.C.D.) A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations, and produce certificates of having completed the following curriculum :—1. One Winter course in midwifery. 2. Six months' practice in a recognised lying-in hospital or maternity. 3. A Summer course in obstetric medicine and surgery. 4. Two months' practice in the Cow-pock Institution. Graduates of medicine of M.D. standing may present themselves for examination without complying with Regulations 3 and 4. Fee for the degree of M.A.O., £5.

UNIVERSITY LICENCES.

Candidates for the licences in medicine or surgery must be matriculated in medicine, and must have completed *two years in Arts.*

Licentiate in Medicine.—The course and examination are the same as for the M.B. An L.M. on proceeding to the degree of B.A. may become an M.B. on paying the fees without further examination. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in medicine, £5.

Licentiate in Surgery.—The course and examination necessary for the Licence in surgery is the same as for the degree of Bachelor in surgery. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in surgery. £5.

MEDICAL SCHOLARSHIPS.

Two Medical Scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects :—Anatomy and physiology, chemistry, materia medica, botany, experimental physics, and comparative anatomy.

The board of Trinity College have recently passed orders —1. That three-fourths of the lectures must be attended. 2. That a daily roll be called by each Professor.

Students entering for demonstrations and dissections are required to pay £8 8s. before November 25; dissections only, £5 5s.; demonstrations only, £3 3s.; fourth year's dissections, £2 2s.

THE QUEEN'S UNIVERSITY IN IRELAND.

DEGREE OF M.D. AND M.CH.

THE Queen's University will continue to exist until the Royal University be in a position to confer Degrees; and the Act provides that all terms kept and examinations passed by graduates and students of the Queen's University and Queen's Colleges shall be deemed to be terms kept and examinations passed in the New University.

Each candidate for the M.D. degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts. 2. To have attended in one of the Queen's Colleges lectures on one Continental language for six months, and on natural philosophy for six months; also two Medical Courses. For the remainder of the medical courses, certificates will be received from any recognised lecturer. 3. To pass three University Examinations.

The Medical Curriculum is divided into two periods of two years each.

The first periods comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy and Materia Medica, Practical Chemistry in a recognised laboratory, and six months of a medico-chirurgical hospital.

The second period comprises Anatomy and Physiology, Practical Anatomy, Surgery, Midwifery, and Diseases of Women and Children, Medicine, Medical Jurisprudence, Practical Midwifery, and eighteen months' Hospital Practice.

At least two of the above courses of lectures must be attended in some one of the Queen's Colleges.

The University Examinations are held twice in each year, in June and September.

Each candidate for examination must forward to the Secretary, before the 20th of May and 20th of August respectively, notice of his intention to offer himself, along with his certificates.

THE FIRST UNIVERSITY EXAMINATION IN MEDICINE comprises a modern language, Experimental Physics, Zoology, and Botany.

Students may present themselves at any time after the close of the first winter session. Before being admitted to examination each candidate must produce evidence of having completed the prescribed course.

THE SECOND UNIVERSITY EXAMINATION IN MEDICINE comprises the following subjects :—Anatomy, Physiology, Materia Medica, and Chemistry, to which will be added Zoology and Botany in the examination of candidates who have not previously passed the first examination. Such candidates may either undergo their examination in Modern Languages and Experimental Physics as a part of the second examination, or at any time between the second and the degree examination,

Students may present themselves for the second examination at the termination of the first period of the curriculum, or at any subsequent period, but no student can postpone his second examination until he presents himself for his degree examination.

DEGREE EXAMINATIONS IN MEDICINE AND SURGERY AND EXAMINATION FOR THE DIPLOMA IN MIDWIFERY.

The Examination for the M.D. comprises the subjects recommended for study during the second period.

The Examination for the M.Ch. comprises Surgery, including Operative and Clinical Surgery.

The Examination for the Diploma in Midwifery comprises the Theory and Practice of Midwifery, and the use of obstetrical instruments and appliances.

(*See Advertisements of Queen's Colleges, Belfast, Galway, and Cork.*)

Official regulations may be obtained from G. J. Stoney, Esq., Queen's University, Castle Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

LETTERS TESTIMONIAL, OR THE L.R.C.S.I.

THE examination is divided into two parts, known as the first and second halves.

The junior class must produce certificates of—

a, Preliminary examination, including Greek; *b*, three courses of lectures on anatomy and physiology; *c*, three on practical anatomy, with dissections; *d*, two on chemistry; *e*, one on materia medica; *f*, one on botany, and *g*, one on forensic medicine. This class is examined on anatomy, histology, physiology, materia medica, and chemistry.

The senior class must produce certificates of—

a, Three courses on surgery: *b*, one on practice of medicine; and *c*, one on midwifery; also attendance on a recognised hospital for three winters and three summer sessions. This class is examined in surgery, operative surgery, and appliances, practice of medicine, medical jurisprudence, and prescriptions.

The fees are: £5 5s. as registered pupil of the College; £5 5s. for the Junior Class Examination, which is not returned in case of rejection, but is allowed in the fee for his second examination; £15 15s. for the Senior Class Examition—total £26 15s.

Pupils *who neglect registering themselves previous to going in for the preliminary examination*, must pay £1 1s. for that examination, to which, however, registered pupils, in addition to their own privileges, are free.

Every candidate rejected at the quarterly examination is required to pay to the College the sum of £2 2s. on applying for re-examination.

Method of Examination.—Candidates must lodge their fees and certificates one week before the day.

JUNIOR CLASS.—The candidates are examined in alphabetical order, and the examination occupies three days: 1st day, dissections; 2nd day, written examination on anatomy, physiology, histology, materia medica, and chemistry; 3rd day, *vivâ voce* examination on the same subject. No candidate can proceed to the second day who has not passed the first; or to the third, who has not passed the second.

SENIOR CLASS.—The examination occupies four days; 1st day, written examination on surgery, practice of medicine, medical jurisprudence, and prescriptions; 2nd day, *vivâ voce* examination on surgery and practice of medicine; 3rd day, clinical examination; 4th day, operative surgery.

No candidate can present himself for examination after the first day who has not satisfied his examiners upon the previous day; but all candidates who have passed any day's examinatfon get credit for same. When presenting themselves upon a subsequent occasion, a former candidate is only required to present himself upon that portioon of the examination in which he has failed.

Midwifery.—After passing the L.R.C.S. the student is admitted to examination for diploma in Midwifery upon producing a certificate of one course on Midwifery and Diseases of Women and Children; a certificate that he has attended a lying-in hospital for six months; and a certificate that he has conducted thirty labour cases at least. Candidates are examined on the Organisation of the Female, the Growth and Peculiarities of the Fœtus, the Practice of Midwifery, and the Diseases of Women and Children. The candidate pays £1 6s. for the Midwifery diploma, provided he takes it out within one month from the date of his Letters Testimonial; after that date, £2 2s. Official information may be had on application to Mr. J. Brennen, Royal College of Surgeons, Dublin.

DENTAL REGULATIONS.

During 1878 the Council has under the authority of the Dentists' Act created a new license in dental surgery. The examiners shall consist of three fellows of the College, three registered dentists, and the president, vice-president, or other member of the Council of the College (summoned in rotation).

The board has the absolute power to refuse the application of any candidate.

The examinations, up to the first day of August, 1881, shall be of a practical character, embracing the anatomy, physiology, surgery, and pathology of the teeth, jaws, and surrounding parts, and mechanical dentistry; and shall be partly written and partly oral.

All candidates shall lodge at least one fortnight previous to each examination.

I.—A certificate of having attained the age of 21 years.

II.—Certificates from two fellows or licentiates of any College of Surgeons in the United Kingdom, and from two dentists of repute, testifying that the candidate is of good character, has been engaged in the practice of dentistry for at least five years, and has refrained from advertising or other unbecoming modes of attracting business for at least two years previously.

III.—Receipt for the fee of ten guineas.

After the 1st day of August, 1881, no candidate shall be admitted to examination who has not pursued the following curriculum, and lodged with the registrar of the College, at least a fortnight previous to examination—

I.—A certificate of having attained the age of 21 years.

II.—A certificate of having been engaged during four years in the acquirement of professional knowledge.

III.—Certificates of character as above.

IV.—A certificate of having passed the examination in preliminary education.

V.—A receipt for the fee of ten guineas.

VI.—Certificates of having attended in a recognised school—one course of lectures on anatomy and physiology, two courses of dissections, with demonstrations, one course of lectures on surgery, one course of lectures on chemistry, one course of practical chemistry and metallurgy, one course of lectures on materia medica, and two courses of lectures on dental surgery, including dental mechanics.

VII.—Certificates of having attended general hospital practice for two winter sessions; and the dental department of a general hospital, or a special dental hospital, for a further period of nine months.

VIII.—A certificate of having been engaged during, at least three years, in acquiring a practical knowledge of dentistry, under the instruction of a registered licentiate in dentistry of one of the licensing bodies.

The examinations shall include all the subjects of the foregoing curriculum, and shall be partly written and partly oral, preparations, microscopes, and other appliances being used.

N.B.—Every successful candidate, previous to receiving the license, shall declare that he will not advertise or pursue any other unbecoming mode of attracting business, so long as he holds the license in dentistry of the College.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

THE MEMBERSHIP.

[*Under the Provisions of the Supplemental Charter of December 12th*, 1878.]

I.—The grade of members is distinct from that of the fellows, and the members as such are not members of the Body Corporate.

II.—Members alone are eligible to the Fellowship. They have the use of the reading rooms and library.

III.—Licentiates admitted before December 12th, 1878, are entitled to be admitted members of the College without payment or examination, on giving six weeks' notice, in writing, to the Registrar.

IV.—Every candidate for membership must produce evidence—

1. Of being over 25 years of age.
2. Of being a licentiate of the College for three years at least; or, a licentiate of one year's standing, if also Graduate of Arts; or, a licentiate of one year's standing, if also a registered practitioner of seven years' standing at the time of his obtaining the license.
3. Of professional conduct and moral character.
4. That he is not engaged in trade; and that he does not directly or indirectly vend medicines or drugs; and that he does not dispense or compound medicines for anyone—even his own private patients—(except in cases of extreme

urgency); nor practise medicine or surgery in partnership, by deed or otherwise.

5. Of having attended courses in ophthalmology and histology.

6. Of having been for six months resident physician, or resident pupil, in a recognised hospital; or for same period as clinical clerk in the medical wards, or in medical charge, for at least twelve months, of any public institution for the treatment of the sick.

7. Of having paid the fee of twenty guineas.

V.—Every candidate must pass *Examination in the following subjects* :—Medical Anatomy, Pathology, Histology, Medical Chemistry, Forensic Medicine, Principles of Public Health, including Climatology and Meteorology, Psychology, and Clinical Medicine.

He shall also be required to translate into English a passage from a Latin author, or to show that he possesses a knowledge of Greek, or French, or German.

VI.—The examination shall be as follows :—Wednesday, Papers of four questions.—Medical Anatomy, Medical Chemistry and Forensic Medicine, Pathology, Psychology. An hour and a-half allowed to each paper.

Thursday.—*Morning—Clinical Examination.*

Afternoon.—The Oral Examination.—This examination includes the investigation of morbid specimens, the qualitative analysis of animal products, the detection of poisons, and the use of the microscope, as well as that in classics and modern languages.

LICENSES IN MEDICINE AND MIDWIFERY.

I.—Examinations for the licenses of the college in medicine and midwifery are held in the week following the first Friday in each month, except August and September.

II.—Every candidate for either license must return his name to the registrar, and lodge his certificate, bank receipt of fees, and his schedule at least *four* days before the first Friday in each month.

THE LICENSE IN MEDICINE.

Every candidate is required to produce satisfactory evidence :—

1. Of character, from a Fellow of the College, or from two registered practitioners.

2. Of having passed an examination in general education, held by some of the recognised examining bodies.

3. Of having been engaged four years in the study of medicine.

4. Of having attended lectures on the following subjects, at recognised schools—

Practical Anatomy, two courses. Physiology or Institutes of Medicine, one course. Chemistry, one course. Practical Chemistry, one course. Materia Medica, one course. Medical Jurisprudence, one course. Practice of Medicine and Pathology, one course. Surgery, one course. Midwifery, one course.

5. Of twenty-seven months a recognised Medico-Chirurgical Hospital, in which Clinical Lectures and Clinical Instruction in Medicine are given, the attendance not to be for more than nine months in any one year, and of having not less than three months studied fever in a recognised clinical hospital, containing fever wards, and recorded, from daily personal observation, at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature. [This rule, with respect to fever cases, to come into force on and after January 1st, 1881.]

6. Of having attended practical midwifery and disease of women for six months at a recognised Lying-in Hospital, or Maternity; or, where such hospital attendance cannot have been obtained during any period of the student's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding public appointments; not less that twenty labour cases to be actually attended.

III.—The professional examination is divided into two parts :—

First Part.—Anatomy, Physiology, Chemistry, and Materia Medica.

Second Part.—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

IV.—Any registered practitioner of *five* years' standing shall be admitted to examination for the license of the College, on producing his certificate of registration, with satisfactory reference, and shall have the privilege of being exempted from the examination by printed questions.

Each candidate shall be examined separately, and shall be required to recognise pathological specimens, and undergo such other practical tests as the examiners shall select.

THE LICENSE IN MIDWIFERY.

Candidates for the license in midwifery, who are not licentiates in medicine, may be admitted to examination on the following qualifications :—

(1) The degree or license from any University or College in the United Kingdom; (2) Testimonials as to character; (3) Certificates of having attended (a) a course of lectures on midwifery in a school, recognised by the College (see Rule III). (b) Practical midwifery and diseases of women, for six months, at a lying-in hospital, or maternity recognised by the College; or where such hospital attendance cannot have been obtained during any period of the candidate's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment,—the certificate, in eitner case, to state that not less than twenty labour cases have been actually attended.

Candidates who are already licentiates in medicine of the College, or who have passed the examination for such license, may be admitted to examination for the license in midwifery on lodging their fees, and signifying their wish to the Registrar a week at least before such examiuation

X.—Any registered practitioner of *five* years' standing shall be admitted to examination for the license in midwifery, on producing his certificate of registration, with satisfactory reference; and he shall have the privilege of being exempted from the examination by printed questions.

FEES FOR LICENSE AND EXAMINATIONS.

XI.—License in medicine, fifteen guineas, which may be divided as follows, viz. :—

For examination at the termination of the first period of study, five guineas.

For final examination for the license, ten guineas.

XII.—License in midwifery, three guineas.

XIII.—Fee for examination of the licenses in medicine and midwifery, if obtained within the interval of a month, sixteen guineas—to be lodged in one sum.

XIV.—Fee for special examination for the license in medicine, twenty guineas.

XV.—Fee for special examination for the license in midwifery, five guineas.

XVI.—Fee for examination for the license to practice as a midwife and nurse-tender, one guinea.

THE APOTHECARIES HALL, IRELAND.

THE ARTS EXAMINATIONS

Will be held at the Hall four times in the year—viz., the third Thursday in the months of January, April, July, and October, at the hour of twelve o'clock, noon.

The examination for *the License* is divided into two parts :—

The First Part comprehends Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy.

The Second—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

THE PROFESSIONAL EXAMINATIONS

Will be held quarterly, on the first and second Monday in January, April, July, and October.

The First Part on the first Monday, at eleven o'clock, noon, and on the Tuesday and Wednesday succeeding at the same hour.

Subjects.—Chemistry and Botany, Monday; Anatomy and Physiology, Tuesday; Materia Medica and Pharmacp, Wednesday.

The Second Part, or Pass Examination, on the second Monday, at eleven o'clock, a.m., and on the Tuesday and Wednesday succeeding at the same hour.

Subjects.—Medicine and Surgery, Monday; Midwifery and Diseases of Women and Children, Tuesday; Forensic Medicine and Hygiene, Wednesday; Clinical Examination, Thursday.

The first three hours of each day will be devoted to writing answers, and afterwards there will be two hours to an oral and practical examination.

Candidates at the examination on Anatomy are liable to

be called on to perform dissections; and at the examination on Surgery to perform one or more operations on the dead subject.

Doctors of Medicine and Licentiates of a College of Physicians who have also spent twelve months at Practical Pharmacy, may obtain the License by undergoing an examination —the former in Surgery and Pharmacy and the latter in Medicine and Pharmacy. Licentiates of the London Society of Apothecaries must undergo an examination in surgery.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The above Society was instituted by the Pharmacy Act (Ireland), in 1875, 38 & 39 Vict., cap. 57. In that Act it is stated that whereas a great deficiency existed throughout Ireland, of establishments for the sale of medicines and compounding of prescriptions, and that great inconvenience therefore arises to the public, it is expedient to amend the Act of 1791 (the Apothecaries Act). A president (Sir Dominic Corrigan) and vice-president (Dr. Aquilla Smith), with a council of twenty-one men, were named by the Government to carry out the provisions of the Act. In 1878 Sir Dominic Corrigan resigned the presidentship. The present president is Professor Tichborne, and the vice-president Dr. Aquilla Smith. The pharmaceutical chemist is not allowed to prescribe, but must strictly confine himself to the compounding of prescriptions. In this respect he differs from the apothecary. All persons who keep open shops for compounding prescriptions must hold the license of the Pharmaceutical Society or the Apothecaries' Hall. The Society, according to their Calendar, which was corrected to the 31st December, 1879, had 167 licentiates. They hold evening meetings during the winter for the reading and discussing of pharmaceutical papers and scientific papers bearing on pharmacy. This society has power under their Act to prosecute persons illegally compounding.

MEDICAL SCHOOLS AND HOSPITALS IN DUBLIN.

The Clinical Hospitals of Dublin are 10 in number, exclusive of the Cork Street Fever Hospital, 2 Lying-in Hospitals, 2 Ophthalmic Hospitals, the Children's Hospital in Pitt Street, and other special institutions. To some of the Clinical Hospitals Medical Schools are attached; others, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital and any school he wishes.

The Names of the Professors, Lecturers, and Hospital Staff of the following Hospitals and Schools are not included in this column, being found in the advertisement of each institution.

DUBLIN MEDICAL SCHOOLS.

School of Physic.—The Medical School of Trinity College is one of the largest and most important. It is especially frequented by those students who intend to take the Arts Curriculum of the University, but is freely open to, and largely availed of, by other students. It is under the immediate supervision of a Committee of Professors, with Rev. Prof. Haughton as Chairman, and the names of its Professors will be found appended to the advertisement in our journal. Two Medical Scholars are elected annually by the Board of Trinity College, at an examination held at the end of June. Each scholarship is worth £20 per annum, and is tenable for two years.

The Royal College of Surgeons School is situated within the walls of the College, and is under the superintendence of the Council, who appoint the Professors. The Professor of Physiology commences his course with a series of twelve lectures on Comparative Anatomy. The dissecting-rooms have recently been much enlarged, and are lighted with gas for evening work. Prof. Swanzy will give the Introductory Address on Monday, 25th October, at 1 o'clock. The staff of Demonstrators has been recently much enlarged.

The Carmichael College of Medicine and Surgery has been removed from North Brunswick Street to its new premises in Aungier Street. The edifice is now fully completed. As the buildings are entirely new from their foundation, the directors have been able to provide all the most recent improvements, and they have spared no expense to render every department fully adequate to the requirements of the most advanced teaching of Medicine and Surgery. The School is most conveniently situated, being in immediate proximity to the Meath, Adelaide, and Mercer's Hospitals, and it is connected by its teachers not only with these hospitals, but also with those of the House of Industry and the City of Dublin. We would direct attention especially to the dissecting-rooms, and to the physiological laboratory. The former are spacious, well-ventilated, and admirably lighted from the top as well as from the two sides; the latter is completely furnished with every requirement for the practical training of students in physiological and histological research. Two scholarships, the "Mayne" and the "Carmichael," each value £15, and prizes to the value of over £60 on the foundation of the late Mr. Carmichael, are offered annually. The Carmichael Scholarship is for students commencing their third year, and will be examined for in the last week in October. The examination for the "Mayne," and for the other prizes, will not be held until the close of the session.

The Ledwich School was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige. Its name was bestowed upon the school as a tribute of respect to the late T. H. Ledwich, who sacrificed a life in an increasing effort to promote its welfare. It is situated in Peter Street, not five minutes' walk from the College of Surgeons, the Meath, St Vincent's, Coombe Lying-in Hospital, and Mercer's Hospital, and in the same street with the Adelaide Hospital and the Carmichael Medical School, and ten minutes' walk from the Catholic University School, the School of Physic, and the City of Dublin Hospital. An Introductory Lecture will be given at this school by Dr. A. H. Benson, on November 1st.

The Catholic University School is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green. Most of its professors are physicians and surgeons of the Mater Misericordiæ, St. Vincent's, or Jervis Street Hospitals, and its courses of study qualify for admission to all the licensing bodies. The University grants an Exhibition of £20, a gold medal, value £7, and class prizes.

Dr. Steevens's Hospital School has ceased to exist since our last issue.

CLINICAL HOSPITALS.

Sir Patrick Dun's is the hospital attached by Act of Parliament to the School of Physic, and officered by the professors of that school. It was for many years a purely medical hospital, but is now a large medico-chirurgical hospital, with a midwifery maternity attached.

The Meath Hospital, which is also the public infirmary of the county of Dublin, containing 120 beds, and now in the 125th year of its existence, ranks among the oldest of the charitable institutions of this city. It is situated on the side southern of the city, upon about three acres of ground, formerly called "The Dean's Vineyard." The original Meath Hospital, situated on the Coombe, was opened in 1753. The foundation-stone of a new Meath Hospital, on the Coombe (now the Coombe Lying-in Hospital), was laid out by Lord Brabazon, 10th October, 1570: this hospital was, in 1774, constituted the County Dublin Infirmary by Act of Parliament. The present building, in Heytesbury Street, was opened in 1822, since which time the building has undergone considerable enlargements and improvements. In 1830 the theatre for operations and lectures was erected. In 1852-53 the Collis Wards were added as a memorial to Maurice Collis, twenty five years surgeon to the hospital. In 1865 the "Smyly Ward," built for the special accommodation of children, was opened by the Lord-Lieutenant, Lord Woodhouse.

The City of Dublin Hospital is situated in upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons and Trinity College. There are special wards for ophthalmic and aural diseases, on which subjects a special course of lectures is delivered. There is a special ward for

diseases of women, and a course of lectures given on diseases peculiar to women; there is also a ward exclusive for children. The Drummond Wing is set apart for fever and other contagious diseases. Clinical assistants to the physicians and dressers to the surgeons are appointed from the most deserving of the class. Medical and surgical pupils are appointed by examination.

MERCER'S HOSPITAL, William Street, founded A.D. 1750.—This hospital is situated in the centre of the metropolis, in the midst of a densely-crowded population, and its doors are opened at all hours for the reception of accidents and of acute cases. Dispensaries are held daily, and are largely attended. Special instruction is given in cutaneous, infantile, gynæcological and ophthalmic diseases. From the large number of accidents which from its position come to the hospital, students are afforded ample opportunities of rendering themselves familiar with the nature and treatment of disease in its various forms, and of acquiring dexterity in the dressing and manual operations of minor surgery.

RICHMOND, WHITWORTH, and HARDWICKE HOSPITALS.—Accommodation: Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds; total 312 beds. These hospitals are visited each morning at 9 o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, Clinical Lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There is a very large ophthalmic, aural, and dental dispensary, and the respective surgeons give instruction in these important subjects. Eight resident Clinical clerks and the dressers are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not only to advanced students as formerly, but also to those who are qualified in medicine or surgery. A house surgeon for the Richmond Hospital is elected biennually, and receives a salary.

The Richmond Lunatic Asylum, containing 1,000 beds, adjoins these hospitals.

The ADELAIDE HOSPITALS, recently much enlarged, are in Peter Street, next door to the Ledwich School and within a few minutes' walk of the Carmichael Medical College, the College of Surgeons, and the University. From the 1st of October the physicians and surgeons will visit the wards, and give instruction at the bedside, at the advertised hours. There is a large detached fever hospital and also wards for infants and children. Special hours are devoted to clinical instructions in the diseases peculiar to women, and students are individually instructed in the use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope. Three resident pupils are selected half-yearly. Prize examinations including examination for the Hudson Scholarship, £32, are held at the termination of the Session. The large dispensaries afford facilities for the study of the eye, ear, throat, and cutaneous diseases, as well as minor surgery and dentistry.

MATER MISERICORDÆ HOSPITAL.—This is one of the largest hospitals in Dublin; it contains 230 beds; 50 beds are reserved for fever and other contagious diseases. A special course of lectures on fever will be given during the session. A ward has been assigned for the treatment of ophthalmic diseases, in accordance with the requirements of licensing bodies. The Leonard prizes, value of £30, will be given at the end of the winter session. A gold medal of the value of Five Guineas will be given by Dr. Hayden as a special clinical prize at the end of the ensuing session. The Introductory Lecture will be delivered by Dr. Madden, on November 3rd.

ST. VINCENT'S HOSPITAL was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The hospital has 120 beds constantly full, and each sister has charge of about twelve patients. In connection with it is the convalescent home at Lindon Grove, Blackrock. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. Cryan, and Dr. Kehoe. A special ward for the treatment of the diseases of women has been opened under the care of Dr. J. A. Byrne, Gynæcologist to the hospital. The ophthalmic department is conducted by Mr. D. Redmond. The resident officers consist of a house surgeon and two resident pupils. The hospital is visited daily at 9 a.m., and patients are admitted at 10 a.m. Accidents and urgent cases, however, are admitted at all hours. Special arrangements have been made to afford facilities to the students for the study of infectious fevers.

DR. STEEVEN'S HOSPITAL, situated close to the Knightsbridge Terminus of the Great Southern and Western Railway, occupies a position of its own, far removed from the other medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. There is accommodation for residence of seven surgical and four medical residents; besides whom the resident house-surgeon receives house pupils. The fees payable for the privilege of residence are twenty guineas, winter; fifteen guineas summer six months. Students have apartments, coal, gas, and furniture. Accommodation outside the hospital in the neighbourhood, is arranged by the hospital authorities.

JERVIS STREET, HOSPITAL is one of the oldest established charitable institutions in Dublin, having been founded in 1721. It is situated in a part of the city not otherwise provided with hospital relief, and which, from its commercial character, supplies the hospital with an abundance of surgical cases. Its nursing arrangements are under the charge of a community of Sisters of Mercy. The hospital, being found inadequate to the demands upon it, is in process of being rebuilt.

SPECIAL HOSPITALS.

The Special Hospitals of Dublin are the Rotunda and Coombe Lying-in Hospitals, Cork Street Fever Hospital, Pitt Street Children's Infirmary, St Mark's Ophthalmic Hospital, the National Eye and Ear Infirmary, and two Orthopædic Hospitals.

The ROTUNDA HOSPITAL.—This well-known and time-honoured institution posssesses a character as a school of midwifery which needs no comment. It is not, however, as generally recognised as it deserves to be, as also a great school of gynæcology. The institution consists, in fact, of two distinct hospitals, viz., the lying-in hospital, into which some 1,200 cases of labour are admitted annually, and the Hospital for the treatment of diseases peculiar to women, into which some 500 patients are now admitted during the course of the year. The present master, Dr. Lombe Atthill, as is well known, devotes special attention to this department of the charity. There is also a large extern maternity in connection with the hospital. Every facility is afforded for the study of the special departments of medicine to which the hospital is devoted, and both students and midwives are granted a diploma on passing an examination. The clinical clerkship, value £50 a year, tenable for six months, is adjudged, after open competitive examination, to any pupil who has attended the full course of instruction in the hospital.

COOMBE LYING-IN HOSPITAL.—This hospital, which was rebuilt and refurnished some few years ago, contains 65 beds. It was founded in 1826 by Mr. Boyle, and was incorporated by Royal Charter in 1867, thus enabling its medical officers to issue diplomas qualifying the holders to practise midwifery. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It receives about 800 labour cases within its walls, while those attended as extern amount to more than double that number. Moreover, the chronic hospital for the reception of cases of the diseases of females gives admission to about 200 patients annually. The fee for attendance is £8 8s. for six months as extern, and £18 18s. as internal pupil. During that period the student attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. Two resident pupil midwifery assistantships, and a clinical clerkship, are obtainable annually, by competitive examination, for which all pupils who have obtained their midwifery diplomas are eligible. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside. In fact, this hospital is now one of the first clinical hospitals (in this speciality) in Europe.

CORK STREET FEVER HOSPITAL AND HOUSE OF RECOVERY is the only special fever hospital in Dublin. It contains 200 beds, and is supported mainly by an annual Government grant, supplemented by voluntary contributions. A certificate of attendance on fever being now required of candidates for the licence to practice medicine of the King and Queen's College of Physicians in Ireland, arrangements are at present (September, 1880) being made whereby the exceptional advantages connected with this institution will in a short time be utilised for purposes of clinical teaching.

When these arrangements are completed and sanctioned by the managing committee, due notice will be given by advertisement as to the hours of attendance, fees payable, and other details. All particulars may then be ascertained on application to Dr. C. Purcell Atkins, Registrar and Resident Medical Officer.

The Pitt Street Children's Infirmary, established 1821, is situated close to Mercer's Hospital and the College of Surgeons. It was founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill are the the medical officers.

Dublin Orthopædic Hospital. 11 Usher's Island, contains 28 beds for the treatment of every class of deformities and the practice of orthopædic surgery. The Institution is under the management of Mr. Swan.

National Orthopædic and Children's Hospital for the treatment of club-foot, contractions and distortions of the limbs, spinal and other bodily deformities and all non-infectious diseases peculiar to children, 7 Adelaide Road, Dublin. Mr. Ormsby attends on Mondays, Wednesdays, and Fridays, Dr Woodhouse on Tuesdays, Wednesdays, and Saturdays, from 10 to 11 o'clock, and gives clinical instruction on the intern cases. The hospital is capable of containing 30 beds, for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Fridays. Students and practitioners are allowed to attend the clinical instruction.

St. Mark's Ophthalmic Hospital and Dispensary for Diseases of the Eye and Ear.—This is the oldest and largest special ophthalmic hospital in Dublin, and was founded by Sir William Wilde. Clinical lectures are given on the mornings of Mondays, Tuesdays, Thursdays, and Fridays, at 11 o'clock, and operations are performed on Wednesdays and Saturdays at the same hour. A surgeon resides in the institution, and receives a salary of £10, besides room, gas, coal, &c.

National Eye and Ear Infirmary.—This institution is situated in Stephen's Green. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope, will be given during the winter session. The certificate of a three months' course on the eye and ear is now required by the Board of Trinity College for the degree of B.Ch., and by the Council of the Royal College of Surgeons in Ireland, for the L.R.C.S.I.

INTRODUCTORY LECTURES IN THE DUBLIN SCHOOLS AND HOSPITALS.

Royal College of Surgeons—Mr Swanzy; October 25th, at 1 p.m.
Ledwich School—Dr A. H. Benson; November 1.
Carmichael School—None.
Catholic Union School—No information.
Meath Hospital
City of Dublin Hospital—None.
Richmond Hospital—October 28th, at 10-30 a.m.
Jervis Street Hospital—None
Mercer's Hospital
St. Vincent's Hospital—Dr. Quinlan; October 28th, at 11 a.m.
Rotundo Hospital—November 1st, at 10 o'clock.
Mater Misericordiæ Hospital—Dr. Madden; Nov. 5, at 11 a.m.

IRISH PROVINCIAL SCHOOLS.

THE QUEEN'S COLLEGES.

These three important institutions are the special schools of the Queen's University, and are situated in Belfast, Galway, and Cork. When the new Irish University comes into operation the Queen's Colleges will maintain their existence as affiliated colleges. They receive a large subvention from the public funds and are provided with every facility for the education of their students. It is essential that every candidate for the medical or surgical degrees of the Queen's University shall have attended courses of lectures in Modern Languages, Natural Philosophy, and, at lesst, two medical subjects, in one of the provincial colleges, so that attendance at a Queen's College during one of the years of medical study is compulsory upon all candidates for the licenses of this University. A detail of the prizes and exhibitions in arts and medicine, the names of the professors, and other information will be found in the advertisements of this issue, and full details may be had on application to—

Belfast.—John Purser, M.A., Registrar.
Cork.—Alexander Jack, M.A.
Galway.—Edward Townsend, M.A.

TECHNICAL EDUCATION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE.

This College supplies a complete Course of Instruction in Science, applicable to the Industrial Arts, especially those which may be classed broadly under the heads of Chemical Manufactures, Mining, and Engineering. A Diploma of Associate of the College is granted at the end of the Three Years' Course. There are Four Royal Scholarships of the value of £50 each yearly, with free education, including Laboratory Instruction, tenable for two years. Two become vacant each year. They are given to students who have been a year in the College. The Chemical and Physical Laboratories and Drawing School are open daily for Practical Instruction. The Session commences on Monday, October 7th.

MEDICAL EDUCATION IN SCOTLAND.

THE UNIVERSITIES.

The fees for the degrees in all four of the Scotch Universities are the same, viz. : £15 15s. (£5 5s. being payable at each of the three examinations; C.M., £2 5s. (in addition to the fees of M.B.); M.D., £5 5s. (in addition to the fees for M.B.); and £10 for Government stamp.

UNIVERSITY OF EDINBURGH.

This is a qualifying and teaching body, and has complete Faculties of Theology and Law, equally with Medicine. Prior to commencing medical studies the student must pass a preliminary examination in English, Latin, and arithmetic, the elements of mathematics, and the elements of mechanics. An examination in at least two of the following subjects is demanded before being admitted to a professional examination, in addition to the foregoing subjects, viz, : Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy. The University confers three degrees, medical and surgical qualifications being granted—M.D., M.B., and C.M. The C.M. is not conferred unless the M.B. be taken at the same time. For the degrees of M.B. and C.M. four years of professional study must be completed after passing a preliminary education recognised by the Medical Council. A degree in Arts of any British University is held to supersede the preliminary examination. Of the four years of professional study, one must be passed in the University of Edinburgh, and another of such four years must be in some other university entitled to grant the degree of M.D. The M.D. degree is conferred on Bachelors of Medicine who have attained the age of twenty-four years, and who present a thesis to be approved by the Medical Faculty. The lectures of several extra-mural lecturers in Edinburgh, as well as those at the London medical schools, and such teachers in the provincial schools approved by the University Court, are recognised, subject to certain conditions.

UNIVERSITY OF ST. ANDREWS.

This University confers the degree of M.D. (certain exemptions being made to ten practitioners yearly), M.B. and C.M. Two years of study of each candidate must be in one or more of the following Universities, viz., the University of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

The degree of M.D. is conferred on any registered practitioner above the age of forty whose professional position is such as to entitle him to that degree, and who shall, on examination, satisfy the examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section to a greater number than ten in any one year. The examinations are held yearly, towards the end of April.

UNIVERSITY OF GLASGOW.

This is both a teaching and examining body. It confers three degrees, viz. : Bachelor of Medicine, Master of Surgery and Doctor of Medicine. Before graduating the student must have been engaged in medical study for four years, one of which must have been spent at the University of Glasgow, and the others at some university or school recognised by the Glasgow University. A *medicus annus* is constituted by two courses of 100 lectures each, or by one course of 100 lectures, and two of 50 each. Two preliminary examinations must be passed, one before commencing study, and the other before appearing at the first professional examina-

tion. A degree in Arts (not honorary) exempts the student from these examinations.

Bursaries tenable by Medical Students.—The Brisbane Bursary, of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries' value £20 per annum each, open to medical students who have just completed the second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly, for three years, open to students of divinity, law, and medicine, who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the preliminary examination for M.B. The Marshall Bursary, value £17 per annum, and tenable for four years, open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. The Lorimer Bursary, value £50 per annum, tenable by a medical student for three years.

UNIVERSITY OF ABERDEEN.

This University is entitled to confer degrees in all the Faculties, and is a teaching body as well. The curriculum of study is nearly the same as in the University of Edinburgh. One year must be passed at Aberdeen. Another of such four years must be either in this University or in some other university entitled to give the degree of M.D. With regard to fees, each candidate for the degree of M.B. must pay a fee of £5 5s. in respect of each of the professional examinations. If he desires to be admitted to the degree of M.B. only he will not be required to pay any further fee, in addition to the £15 15s.; but on admission to the degree of C.M. he must pay a further fee of £5 5s., in addition to the fees for the M.B. degree. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions. Perpetual fee for hospital practice is only £16. The professional examinations are held twice in each year; namely, in April and July, directly after the close of the winter and summer sessions.

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years, in attendance in an hospital, or in military or naval medical service, or in medical or surgical practice. Provided always that the degree of Doctor of Medicine shall not be conferred on any person unless he be a graduate in Arts, or unless he shall before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examidation in Greek, and in Logic or Moral Philosophy.

THE COLLEGES.

Royal College of Physicians, Edinburgh.—This, like the sister College of London, is exclusively a qualifying body. In conjunction with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Edinburgh, this College grants a double qualification, and registerable as such. Each applicant for professional examination must previously have passed the preliminary examination prescribed by the General Medical Council. Exemption is made in the case of masters or bachelors of Arts, of any British University and certain recognised foreign Universities. Candidates who may have already passed the first professional examination of any body approved of by the College will be at once admitted to the second part of the examination.

The Fellowship is conferred only by election, and the candidate must at least have been a member of the College for one year previously, and have attained the age of twenty-five years.

The Membership is conferred on licentiates of the College, or graduates of the British or Irish University, with whose knowledge the College may be satisfied, and who have attained the age of twenty-four years.

The License.—The regulations are nearly the same as those for the joint examination for the Scotch double qualification.

The professional examination will be divided into two parts, according to the following arrangement of subjects: 1. Anatomy, physiology, chemistry. 2. Materia medica and pharmacy, pathology, and pathological anatomy, practice of medicine, surgery, midwifery, medical jurisprudence, clinical medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing.

Qualification in Public Health.—The College now confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

Fees.—The fee payable by a licentiate is £10 10s. In the case of unsuccessful candidates the fee is returned, minus £4 2s., retained to defray the expenses of examination. The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of a member, he pays £21. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp duty, which amounts to £25. All candidates for fellowship or membership must lodge their fees, and the amount of stamp duty payable at the time to Government, with the treasurer, previously to presenting their petitions.

Royal College of Surgeons, Edinburgh.—Candidates for the diploma of this College must have followed a course of study in some University, or in an established school of medicine, or in a recognised provincial school. Candidates already qualified are admitted on certain exceptional conditions.

Preliminary Examination.—All candidates for the diploma of the College must have passed the complete examination prescribed by the General Medical Council, and have their names inscribed on the register of medical students at the commencement of their medical studies. The preliminary examination of certain recognised bodies is accepted by the College.

Professional Examination.—Candidates commencing professional study after September 16, 1886, must have been engaged, during four years after the preliminary general education, in professional study, which shall include not less than four winter sessions, or three winter and two summer sessions' attendance at a recognised medical school.

Professional Examination.—The professional examination is divided into two, the one oral, the other written. The first examination embraces anatomy, physiology, and chemistry. The second examination embraces surgery and surgical anatomy; also medicine, midwifery, materia medica, and medical jurisprudence; and does not take place prior to the termination of the winter session of the last year of study.

The Fellowship is conferred only on candidates who have obtained a diploma from this College or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians or Surgeons of Glasgow, and who are twenty-five years of age. The election is by ballot and three-fourths of the votes are required to be in the candidate's favour, and he has to subscribe certain bye-laws of the Colleges. Fellows are forbidden to keep open shops, to be connected with secret remedies, or indelicate advertisements or publications.

The Licenses.—The regulations are almost the same as those for the joint examinations conducted by the Colleges of physicians and surgeons.

Dental Diploma.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical school, recognised by the College as qualifying for the diploma in surgery.

THE SCOTCH DOUBLE QUALIFICATION.

The Royal College of Physicians of Edinburgh by a certain arrangement, grants conjointly with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons, after one series of examinations, a double qualification, two diplomas being given and registered under the Medical Act as medical and surgical qualifications, thus: Lic. Roy. Coll. of Phys. Edin. and Lic. R.C.S. Edin., or Lic. Roy. Coll. of Phys. Edin. and Lic. Fac. Phys. and Surg., Glas., according as the case may be.

By the understanding subsisting between these bodies, the College of Physicians take exclusive charge of the

examination in medicine; and the College of Surgeons or the Glasgow Faculty, of that in surgery; whilst departments common to both medicine and surgery are examined by a board in which each body is represented. Such arrangements as these were contemplated by the Medical Act, and authorised by section XIX., and those under consideration were sanctioned by the Medical Council, 7th August, 1859.

Candidates having fulfilled the full curriculum are subjected to two professional examinations. Hereafter the preliminary examination must be passed before commencing professional study, and must be otherwise conformable to the regulations of the Medical Council.

School of Medicine, Edinburgh.—The lectures of this School qualify for the University of Edinburgh and the other Universities, and the Royal Colleges of Physicians and Surgeons, Edinburgh, London, and Dublin, and the other medical and surgical boards.

Royal Infirmary, Edinburgh.—Clinical instruction is afforded at this institution under the supervision of Professors of the University and ordinary physicians and surgeons to the Infirmary. Special instruction is given on diseases of women, physical diagnosis, and diseases of the eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, &c. The perpetual fee in one payment, is £10; the annual fee, £5 5s.; half-yearly, £3 3s.; quarterly, £1 11s. 6d. Separate payments for two years entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

Glasgow Royal Infirmary School of Medicine.—The winter session will commence on October 29th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures are also given on practical physiology, operative surgery, aural surgery, dental surgery, and diseases of the eye. During the summer lectures on insanity are given by Dr. A. Robertson, and the City parochial asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

Class Fees.—For each course, first session, £2 2s.; second session and perpetual, £1 1s. Students who have attended a first course elsewhere can enter on the second course on payment of £1 1s. Anatomy, first winter session, £4 4s.; summer session, £1 1s.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 1s. per session. Lectures on diseases of the ear, £1 1s.; with clinique to those who are not students at the hospital, £2 2s. Clinique on dental surgery free to students of the hospital, to others £1 1s. Lectures on diseases of the eye, £1 1s.

Glasgow Royal Infirmary.—Number of beds 570. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of venereal diseases and the diseases of women, whilst diseases of the eye, ear, throat, and teeth are especially treated at the dispensary. Courses of clinical medicine and surgery are in one at least of the following subjects, viz.:—French, German, Higher Mathematics, Natural Philosophy, and Natural History. Provided also that he shall lodge with the Dean of the Faculty of Medicine a thesis composed by himself, and to be approved by the Faculty of Medicine, on any branch of knowledge comprised in the Professional Examination for the degree of Bachelor of Medicine, which he may have made a subject of study after receiving that degree.

given by the physicians and surgeons, and post-mortem examinations are conducted in the pathological theatre by the pathologists, who also give practical instruction in pathological anatomy and histology.

Appointments.—There are five physicians' and five surgeons' assistants. The appointments can be held for six or twelve months, and are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students.

Fees for hospital practice and clinical lectures, first year, £10 10s.; second year, £10 10s., afterwards free. For six months £6 6s.; three months, £4 4s. Students who have paid 20 guineas at another hospital for its perpetual ticket are admitted six months for £2 2s., or one year for £3 3s. Vaccination certificate, recognised by Privy Council, £1 1s.

Anderson's College, Glasgow.—This is exclusively a teaching body. In addition to its offering excellent opportunities for acquiring a good medical education, instruction is given in the other branches of a liberal education, advantage of which might profitably be taken by medical students generally. The expenses of this institution, as already mentioned, are exceedingly moderate. Extensive opportunities for dissection are offered, under the guidance of the very talented lecturer on anatomy.

In connection with this College, there are five hospitals and dispensaries for special diseases, to all of which students are admitted.

The examination for the Scholarships will take place in the last week in November, 1879.

The Summer Session, at this College begins on the first Tuesday of May, and closes about the middle of July. A lectureship on Aural Surgery has been established. Lectures on Dental Surgery are also given four times weekly. The fee for two years' hospital practice required by the curriculum for the Dental Licence is £10 10s. Fees for Dental Lectures are £2 2s. each course.

Further particulars may be obtained on applying to Dr. A. M. Buchanan, Dean of the Medical Faculty.

NOTICE.—The Editor desires to thank the Deans of the various Medical Schools for supplying him with the information respecting the institutions with which they are connected. [As this number is devoted exclusively to information necessary for students intending to join one or other of the various medical schools; and for those, who, having passed their curriculum, are about to enter into the ranks of the profession, the ordinary matter which fills our columns is necessarily deferred to next week. Should any of our readers desire to present this number to a patient or friend who contemplates sending his son to a medical college, our Publisher will be happy to supply him with a duplicate free of cost.]

WOMAN AS A SANITARY REFORMER. (a)

By BENJAMIN WARD RICHARDSON, M.D., F.R.S.

Two of the wisest of men, and by necessity, therefore, both of them sanitarians, Solomon and Xenophon, have laid down rules bearing on the duties of women who rejoice in being called wives as well as women. (The learned author here quoted many passages from Holy Writ, and from Xenophon's writings, as a text on which to found his discourse.) He then said, we ought not to blame womenkind because it seems that women are behindhand in the work. They are not, in point of fact, behindhand at all ; they are rather the forerunners in the race. Long before the word sanitation was heard of, or any other word that conveyed the idea of a science of health, the good, cleanly, thrifty housewife was a practical sanitary reformer. Nay, if we come to the question of organisation itself, we have in this country, in that admirable institution, the Ladies' Sanitary Association, the first of the great sanitary societies, which by its publications, its practical aid to mothers, its out-door recreative parties to the stived-up children of the metropolis, and by various other means, has set an example which will one day be historical as a part of the great movement in the promotion of which we are engaged. There is not, therefore, one single difficulty in the way of making the woman the active domestic health reformer. The only thing that requires to be put forward is the method of bringing her universally into the work, and, if I may so express it, making the work a permanent custom or fashion, to neglect which would be considered a moral defect. There are in England and Wales alone six millions to be influenced. The first suggestion is that the beginning of the crusade shall be a beginning that shall not drive, but lead ; that shall not dictate, but patiently suggest.

> Women should ne'er be taught a thing unknown.
> It should be credited as all their own.

Nor can any finer or nobler occupation be imagined than is implied under this head of domestic care and nourishment of health. There are women who think it the height of human ambition to be considered curers of human maladies ; content at best to take their place with the rank-and-file of the army of medicine, and not perceiving that the only feature in their career is its singularity, a feature that would itself become lost if the wish of the few became the will of the many. I press this office for the prevention of disease on womenkind, not simply because they can carry it out ; not simply because it pertains to what Xenophon describes as their special attributes, their watchfulness, and their love ; but because it is an office which men never can carry out ; and because the whole work of prevention waits and waits until the woman takes it up and makes it hers. The man is abroad, the disease threatens the home, and the woman is at the threatened spot. Who is to stop it at the door, the man or the woman? The house is her citadel. The majority of women will ask by what process of training can we help towards a triumph of science so beneficent? I devote myself from this point of my discourse to give some answer to that question. I state at once that the training required is simple—beyond simple ; that every woman who wills to go through it may go through it and may become mistress by it of the destinies of the world. Not the Fates themselves were more the mistresses of the destinies of the race than the women of an educated commonwealth who were conversant with the art of the prevention of disease and premature decay. A woman should master physiology so far as to understand the general construction of the human body. She should be rendered fully conversant with the different changes of food that are required for the digestive process in different periods of life ; the extent to which the digestive powers should be taxed in infancy, childhood, adolescence, maturity, first and second decline, and old age. She should

(a) Read at the Annual Meeting of the Sanitary Institute of Great Britain and Ireland, held at Exeter, Thursday, September, 23rd, 1880.

be made aware what substances, taken as food, are of real, and what of spurious quality. She should be taught the relationship which solid foods hold to liquid foods or drinks. She should be told what drinks are foods, and she should specially understand what are the particular foods required for the young during the periods of active growth. In illustration of the value of this last-named fact, it may be stated that if women only knew what foods were requisite to feed the skeleton or bony framework of the living body while that skeleton is in the course of growth, and if she would act upon her knowledge, as she almost certainly would if she possessed it, there would hardly be one deformed child left in the land in one or two generations. Rickets, with all its attendant miseries of bowed legs, crooked spines, and humped backs, would pass away as if by the spell of an invisible enchantress. After the understanding of the digestive system, the woman should learn the principal facts relating to the circulation of the blood, and the blood itself. Nor should she, in respect to the healthy organisation, be less informed respecting that breath of life which is ever being breathed into the living thing by the Eternal Chemist whose constructions and resolutions are the motions visible and invisible of His eternal universe. The complete structure of those breathing lungs should be as plain before her as the outward form of the things she knows best. Equally clear to her should be the leading facts bearing on that receptive system of the body into which the external universe transports itself, and from which, in reflex response, the acts of life, the expressions, the movements, the thoughts, return in wave-like repetition back again, to become themselves external phenomena, linked, as such, with all the visible universe. To the knowledge of nervous function it would be advisable to add to the store of elementary principles a few facts respecting the great glandular system of the body; and of those night and day labourers of the body, the muscles, the women should learn sufficient to be made aware of the advantages of so training the muscles to work that they shall be daily exercised, shall not be subjected to over-strain, shall be equally subjected, as far as possible, to healthful labour. And of the bony skeleton, on which the muscular engines are laid, and which act as the passive framework and levers of the engine, she should gather enough information to be conversant with all its outlines of form and chemical construction. Lastly, the woman should attain so much instruction in reference to the great membranous expanses as to know them also. She should learn the necessity of keeping the functions of the skin in due cleanliness and condition for work, so that the bath should be considered as one of the necessities of the daily life, like a daily meal of cleanly substance. The living house thus generally learned, the Sanitarian helpmate for us who can do so little beyond our suggestion, would be tempted to study, until she completely mastered it, the mysterious construction of that deadly-lively house, which until lately the architect and builder have pitchforked into street and square with facile and contented wisdom of wigwam descent. She would want to learn how the immaculate house is in every room provided with at least moderate ventilation. She would require to find out how most effectively and economically she can maintain in the varying seasons an even and equable temperature. She would aim to consider in what way she could keep the air of the house free of that most objectionable of mischiefs, dust. She would demand to have marked for her on a map or plan the precise position of every drainpipe in the establishment, and would insist, with intelligent skill, on having every drain kept as systematically clean as the china in the housemaid's cupboard or the metal covers that make so many bright and effective pictures over the dresser of the well-arranged kitchen.

She would see, not trusting to the mere word of anyone, that those drains were properly ventilated so that sewer air could never enter the domain except as a burglar might enter by special skill and violence, against which there is no absolute protection. She would learn enough of the chemistry of water, to enable her to determine with as much facility, as she could tell whether a looking-glass is clear enough to reflect back without fault the image of her face, whether a water was wholesome and drinkable; and she would have a sufficient amount of skill to direct how an impure water might be purified and made safe for her and hers to drink and use for all domestic requirements. She would see to it that damp had no place in any apartment. She would insist that where any living thing that ought not to be present house exists in it, that house is unclean, and in some way uninhabitable for health; since health will not abide with anything that is uncleanly. She would see to the biennial purification of the dwelling, as though a Passover were still an universal belief and practice. She would make the very act of cleaning and cleansing clean; she would make the very best places for cleaning and cleansing—the scullery, the landing, the bathroom, the laundry—the cynosures of the household. In the art of perfection or towards perfection of health the educated woman would in her domestic sphere bring her best energies to understand the selection, the purification, the preparation, and the administration of foods and drinks. As she would keep seeds of certain pestilence from her fold, or vulgar poisons that kill outright, and proclaim at once with loud voice, "accidental disease, or murder," so would she do her best to keep out those refined and subtle poisons which, in and under the name of strong drinks, bring silently more accident, disease, and murder into this inscrutable world than all the other poisons put together, unlicensed though they be, and so little liked by the Exciseman, that he would fly them any distance, the Devil himself in company, rather than so much as touch them with his divining rule. That she would acquire a thorough knowledge of the best art of cookery; that she would acquire a good knowledge in choosing foods in season; that she would become an adept in detecting actual wholesome from actual unwholesome foods; that she would find out what foods are most suitable for persons of different age and constitution; and that she would distribute food with well-balanced hand, neither feeding over-indulgently nor parsimoniously, I take for granted. But I expect she would learn to do more than all these things in relation to food. She would be able better than anyone to put to the test the experience whether it is good or necessary to go to the living animal creation at all for human food. I am in doubt. It does not seem to me that man is constructed to be a carnivorous animal. It does not seem clear, putting the anatomical argument altogether aside, that it can be good to go to secondary sources of supply for our food when Nature bountifully presents them to us from her prime source. It does not seem reasonable that we should employ millions of living laboratories for our daily food, and take the risks of disease which they in endless forms produce and propagate for us, when we can get all that is necessary without the chance of such production and of such propagation. It does not seem certain, when we know that the vegetable world is the original source of every particle of living food, and that carnivorous animals have to depend on the herbivorous for their supplies—so that carnivorous feeding is an anomaly rather than a basic principle of nature—it does not, I repeat, knowing these things, seem certain that the cost of the support of the living laboratories is justifiable on any ground except the extravagant process of making work that work may be at hand and employment procurable. Still I am not sure whether the necessity for the secondary supplies of food for man from the animal world are or are not necessary, and that doubt it is in the *rôle* of the educated woman to solve. Her discernment, properly and eagerly directed, would soon settle whether those about her were injured or benefited by an exclusive vegetable and fruit diet. It has been one of the endeavours of my life to show that we living men and women make in our own corporeal structures a refined atmosphere, which I have called a nervous atmosphere, or ether—an atmosphere which, present in due tension, distinguishes life; which, absorbed or condensed, distinguishes death; an atmosphere through which the external world vibrates and pierces us to the

soul; an atmosphere which, pure and clear, brings us peace and power, and judgment and joy; an atmosphere which, impure and clouded, brings us unrest and weakness, and instability and misery.

We make it from foods and drinks, and as we make it, it makes us. Go into the wards of a lunatic asylum, and notice amongst the most troubled there the odour of the gases and the vapours they emit by the skin and breath. That odour is from their internal atmosphere, their nervous ethereal emanation. They are mad; mad, we say, up to suicide, or murder, or any criminal folly. Can it be otherwise? They have secreted the madness; they are filled with it; it exhales from them. Catch it, condense it, imbibe it, and in like manner it would madden anyone. See, from the study of foods, out of which the radiant or deadly atmosphere is made, what fields of discovery open to the mind. A mother, watching the effect of food on her gloomy saturnine child, may detect how she can so feed it that the cloud shall pass away. Happy mother of a child? Far, far happier mother, perchance, of science and hope. In some great establishments for the insane so much gloom is secreted in the nervous recesses of human frames, that many times a day, but for excessive vigilance, some terrible hand would raise itself against itself, to kill itself. What if in a wiser day, however far off, the removal of that little cloud from a troubled child should show the way to the removal of those denser, blacker clouds which lower and create storms in human breasts, overpowering altogether the radiant nervous ether! What if from that minor event this greater one should follow! What nobler accomplishment of noble deed could woman perform, save and except when she is the mother of her kind? Women should know the correct names and characters of the more common diseases, and they should know, by sight, the every-day contagious or communicable diseases. All the best known methods of preventing disease should be at their fingers' ends, and the rule of the sick room should be their faithful care. The woman should know everything about registering the temperature of the sick room and degree of humidity; the mode of ventilation; the different special methods of feeding, washing, and changing the sick; the most efficient means of disinfecting, and of removing or destroying the poisons of the communicable diseases. How in this way the woman could help the physician, none but the physician can understand.

> Truth can never he confirmed enough,
> Though doubt should ever sleep.

I declare it again, that if, in the management and treatment of any of the acute and of many of the chronic diseases, you gave me, in this climate, absolute control of the fire and the window of the sick room, I could determine the course of the illness. There is no department of practice more neglected, in respect to principles, than the management of offspring in its earliest youth. Love there is plenty of; admiration unbounded; rational systematic training the poorest that can be described. Woman, in addition to instruction on all the points above named, should understand the little appreciated law of temperaments; the nervous, the bilious, the sanguine, and the lymphatic. She should study the combinations of these, and she should observe how temperament influences health, taste, activity, and disease. From this she would learn how different natures would intermix in work or play, and what work, what play, would suit the nature. The sanguine child, ruddy and red, with blue eyes, red hair, strong muscle, quick movements, restless limb, she may set to study at books, while she curbs exercise, with no fear that books will kill, for it will outlive any book. The bilious child, with dark eyes, dark skin, black hair, stolid expression, thoughtful brow, she will not set to the study of books as the work of life; for books may kill; physical exercise may save, but will never be carried voluntarily to injury. The nervous child, with fair skin, light hair, blue eye, quick but feeble movement, timid glance, yet, perhaps, unbounded ambition, she will spirit gently; will balance between physical and mental labour; will apportion excess of neither, and will never urge unduly to any effort. The lymphatic child, large of body, pale, with grey or blue eyes, brown hair, shambling step, watery lip, and slow determination, she will rouse to action, both physical and mental, with the full assurance that neither effort will do anything but good. Beyond the study of the temperaments and the special dangers connected with them, she should devote her mind to the consideration of what the learned D'Espiné has designated the mental contagions. She should study emotional contagion with special care, and on one emotion, that of fear, she should keep the most watchful observation, because she will discover it to be the most common and disastrous of all contagions. She will never excite it for a moment by story of superstition or dread. Finally, in physical psychological training there would stand out for contemplation, and action founded upon it, one more subject: that marvel of the marvellous in living phenomena heredity of type and action, extending to health, and extending, alas! to disease in its deepest foundations. She should stand to resist with her full persuasive might that process which I have elsewhere called the intermarriage of disease. She will tell her sisters what that terrible process means. She will tell that diseased heredity united in marriage means the continuance of the heredity as certainly as that two and two make four; that madness, consumption, cancer, scrofula, yes, and certain of the contagious diseases, too, may be perpetuated from the altar; and that the first responsibilities of parents towards the offspring they expect ought to be, not how to provide for wealth and position over which they have no control, but that preliminary health parentage, which is the foundation of health, and without which position and wealth are shadowy legacies indeed. Delicate ground, you may say. I admit the fact. But in a world in which those who study the living and the dead most carefully rarely see a man or woman hereditarily free from disease, even this ground must be entered on by the enlightened scholar. I touch on it here for the best of all reasons, that the subject it includes, affecting deeply the human heart in its sympathies and affections, is one on which the influence of woman the arbitress of the natures that are to be, is all potent for good or for evil. To know the first principles of animal physics and life; to learn the house and its perfect management; to learn the simpler problems relating to the fatal diseases; to ordain the training of the young; to grasp the elements of the three psychophysical problems; the human temperaments, the moral contagions with their preventions, and the heredities of disease with their prevention—these, in all respect and earnestness, I set before this Congress as the heads of the educational programme for our modern woman in her sphere of life and duty. Let these studies be hers, and once more may be applied to her the promise of that wisest of men, with whose words I opened this discourse: "She shall rejoice in time to come. The heart ot her husband doth safely trust in her." And—sun and sum of all hopes, ambitions, happiness!—"Her children shall rise up and call her blessed."

THE NECESSITY AND IMPORTANCE OF MORTUARIES FOR TOWNS AND VILLAGES, WITH SOME SUGGESTIONS FOR THEIR ESTABLISHMENT AND MANAGEMENT. (a)

By HENRY C. BURDETT,
Greenwich Hospital.

THE subject of mortuaries is one that has received by far too little attention at the hands not only of those who are responsible for the practical carrying out of the pub-

(a) Abstract of a Paper read at the Annual Meeting of the Sanitary Institute of Great Britain and Ireland, held at Exeter, Wednesday, September 22nd, 1880.

lic health laws of the kingdom, but even of ardent sanitary reformers. Yet it holds, or ought to hold, a prominent place in preventive medicine; and it differs from other sanitary appliances in having an important moral and social office as well as a hygienic one. Most of us, and especially those whose work has brought them into relations with the poor and the degraded, know what additional terrors death brings with it when it occurs in wretched tenemented property, or in overcrowded cottage homes, where the same room has to act as dead-house, living room, work-room, and not infrequently bed-room. In the poorer parts of our great towns, and, to a lesser degree, perhaps, in country villages, scenes of the most harrowing and saddening description are constantly being enacted through the unavoidable presence of the dead in the midst of the living. Our veteran vice-president, Edwin Chadwick, wrote most fully on the subject so long ago as 1843. Cases are constantly occurring in the experience of London coroners, whose evidence on this subject would be of the most instructive and startling kind. The dead body of a woman on whom an inquest was held by Dr. Hardwicke in 1876 was kept in a miserable underground kitchen where the family lived; and where, after the work, the family slept and took their food by the side of the corpse until the burial took place. At a meeting of the West Derby Local Board in March, 1876, the sanitary inspector reported that in the course of his duties he had visited a house on the 23rd, and had found the body of a woman who had died on the 19th lying in one of the rooms which was used as the sleeping-room of the family. The husband stated that as he was too poor to inter the body, he had applied to the relieving officer to have it buried, but the request had been declined by the board of guardians. He then went to the clerk of the Local Board, who, after some delay, got an order from a magistrate, and the body was buried six days after death. The husband, who was represented to be given to drink, and indifferent as to whether the body was buried or not, had slept, it was said in the same bed in which the cerpse lay.

All sanitarians agree in thinking that in large or crowded towns a properly constructed mortuary is of the first necessity; and there are reasons for thinking that in rural districts also some provision of the kind would be extremely valuable and save much present scandal. The dwellings of agricultural labourers and their often indecent overcrowding need no description at my hands; and what is to be done in such when a death occurs? Evidently the dead must be left in very unwholesome and distressing proximity to the living in the absence of a mortuary or dead-house, which thus becomes a necessity throughout the country. The remedy is the provision of reception or dead-houses, in which corpses may remain pending interment.

Mr. Burdett then sketched at length the various attempts made by the Legislature to deal with the question of mortuaries during the years 1840-1880. Of mortuaries proper, all sorts and sizes exist, from the elaborate erection provided at a cost of £12,000, by the City of London Commissioners of Sewers, in Golden Lane. The speaker then graphically sketched the features of a properly-constructed mortuary, and gave many interesting details as to its establishment, situation, and the regulations for its conduct.

With reference to hospital mortuaries, he made the following practical suggestions:—Most hospitals make some sort of a provision for deaths occurring within their walls; and I think that if sanitary authorities felt disposed to help, hospital managers would often be found willing to erect a somewhat more pretentious mortuary than they would otherwise have done, and to throw it open, under certain regulations, to the general public. The rapid extension of cottage hospitals leads one to hope that this method of securing mortuaries would satisfy the demands of a large and increasing number of places. It is a common practice for local authorities to subscribe to hospitals —especially to infectious hospitals— provided by private enterprise; and I am not aware of any legal objection to the same power of subscription being exercised in the case of mortuaries. Indeed, the utility of a mortuary is usually more obvious to local authorities than that of a hospital, so that probably this plan has only to be suggested to secure adhesion to it. Mortuaries in cemeteries next claimed attention, and the valuable evidence given by the late Mr. Robert Baker was enforced. The disinfections, fittings, and rules for burial were fully described, and the speaker further insisted that the post-mortem room may adjoin, but should be quite distinct from, the mortuary. The hours during which bodies ought to be received, the necessity of having free mortuaries, the regulations as to the visits of friends, and the provision of a separate chamber for infectious cases were then fully entered into.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

An Acute Case of Addison's Disease.

Under the care of Dr. DYCE DUCKWORTH.

Communicated by Mr. SIDNEY DAVIES, Clinical Clerk.

G. WILLIAM S., æt. 20, a pressman, was admitted to St. Bartholomew's Hospital, on August 19, complaining of headache, giddiness, and nausea. He gave the following account of himself:—

About a month ago he noticed that he came home from his work quite exhausted. Shortly after, his friends observed a darkening of his complexion. For a month past he has been getting progressively weaker, and losing flesh. Previous to his present illness he had been well and strong, except for two attacks of rheumatism (whether acute or chronic, unknown). He had rheumatic pains in his thighs two weeks ago, which confined him to bed for a week. He knew of no special disease among his relatives, so that no help to diagnosis could be obtained from his family history.

On admission, he was found to be in a state of great weakness, and his muscles were much wasted. But the noticeable feature about him was the bronze colour of the face, which at once attracted attention; though it might have appeared natural in a country labourer, it seemed very unnatural in a delicate-looking Londoner. This bronze tint also pervaded the skin over all his body, but was specially marked on the areolæ and nipples, navel, scrotum, and prepuce; after these, the abdomen, palms, and flexor surfaces of arms were most pigmented. Lines of pigment were also seen on the mucous membrane of his cheeks. The conjunctiva was rather anæmic, and the pupils contracted. Temperature, normal; pulse, weak—beating 72 per minute.

The heart and lungs were normal. On palpating the abdomen, tenderness was found in the epigastrium, but at that time he had no pain in the abdomen, or loins. No tenderness or other abnormal feature was discovered in the region of the spine.

He stated that his appetite was generally bad, but had improved a little since entering the hospital. He slept pretty well. The urine was normal. A microscopical examination of the blood was made a few days after admission; the most marked abnormal feature was the absence of any tendency in the red corpuscles to form rouleaux, and the absence of the dumb-bell shapes commonly presented by red corpuscles seen on edge: besides this, the white corpuscles appeared to be more numerous, and more granular than normal, and there was much *debris* of degenerated leucocytes.

Up to the 25th the patient appeared to be improving; he got up and went about the ward, and only occasionally felt giddy after the exertion of rising. He felt better, and ate and slept well. But on the 26th he first felt a pain in the umbilical region, accompanied by nausea. This continued, and was soon followed by vomiting after taking food. Nutrient enemata were tried without success, and the patient quickly showed signs of inanition; the pulse quickened each day, his extremities became cold, his breath fœtid, and on the 1st September he died. Before death the pigmentation had greatly increased, especially over the abdomen.

Notwithstanding the most urgent entreaties a post-mortem examination was refused.

The only medicines administered, besides aperients were perchloride of iron, ℥xx, and infusion of calumba ; a meat diet was used.

THE PHILOSOPHY OF SLEEP AND DREAMS.

By M. DELBOEUF.

Translated from the *Revue Philosophique*.

By EDWIN JACKSON, B.A., M.R.C.S.,
Manchester.

PART I.

CRITICAL SKETCH OF SOME RECENT WORKS.

III.

(*Continued from page* 219.)

In the course of the chapter M. Radestock gives us thus one by one the particular characteristics which distinguish dreams from objective ideas. He will still talk, for example, of the notion of causality in the dream, of immorality in the dream, and under this head he will examine how far we may be considered responsible for what we do during sleep. He will remark how habitually, except in the case of children, dreams are fugitive, and leave little hold for the memory. He next proceeds to treat in two pages of the *illusion* of which dreams make us the sport—in this respect dreams are in effect distinguished from the other products of imagination in which we without difficulty recognise a character of unreality. Now in my opinion this is a capital, essential, fundamental part in every theory of dreams, and the author passes over it too lightly ; not that he does not on this as on every point say some good things, but he does not settle all my doubts. We will let him speak.

Besides the faculty of *comprehension*, consciousness possesses the no less important faculty of *distinction :* man separates his "representations" one from another ; in the assemblage of his psychical activities he distinguishes the lasting groups and the particular and variable impressions ; he classifies and arranges his ideas from certain points of view in definite circles in which he puts only similars and rejects the dissimilars. He can distinguish between the feebler images of his memory and the present sensations, which are stronger ; and among these latter between those which are furnished to him by his own organism and those which come to him from without. Thus he learns to oppose his own body to the external things which affect it, and his own proper *ego* as concerns the sum of the bodily impressions and psychical activities to the other beings to which he grants an independent reality like his own. Thus he knows in the waking state and in health that a recollection is a different thing from an intuition, and he can *in most cases* distinguish a product of his imagination from something which has an existence, although he cannot always clearly judge between that which is peculiarly objective and that which is peculiarly subjective, in every "representation." But it is otherwise in a dream, or in delirium : here the exaltation of the central nervous activity (is it not a pity to see mere *words* in place of a true explanation ?) lends to the products of fancy a vivacity which is ordinarily the property only of immediate impressions, and which annuls the activity of the soul. We consider as true what our imagination presents to us, the past becomes present, we take our hopes and our desires for facts, absolutely impossible monsters for realities. Sometimes the same thing happens to us when, without our being asleep, we allow ourselves to be the willing dupes of the illusions of our imagination. But these cases are rare, "because recollections have not altogether the force of immediate impressions, and we possess the faculty of setting ourselves right by the real world." In sleep, on the contrary, we receive from without only enfeebled impressions, for were they to be strengthened ever so little they would waken us ; they are incapable of making consciousness act again, and the dreamer, without any information as to the world he lives in, builds himself another out of his own ideas. Hence the dictum of Heraclitus quoted above, that in sleep every one has his own world to himself, whilst when awake the same world is common to all of us. Towards morning only, on the approach of our awaking, we again become sensible of external things, the higher activities of the mind are set in motion, and the illusion vanishes.

I have reproduced this passage almost at full length. As we look at it, it seems very well put ; some will think even that there is nothing to add to it ; and for my part the sentence which I have put in inverted commas seems to me to contain the principle of the solution. However, I stop. Here I am, before my table, which is covered with papers, and I write these lines which the reader has under his eyes. I do not think that I am the subject of a dream ; but, as Descartes says, I have sometimes dreamt something similar, while remarking to myself further, in my dream, that I was not dreaming. Only quite lately I had an extremely complicated dream, quite connected, and very interesting : then I felt suddenly that it deserved to be made a note of, and still dreaming, I carefully put it down on a sheet of blotting-paper. Am I not still dreaming, at the moment when I am writing on ordinary paper ? Some one will tell me that I can put myself right by the external world, which is quite true ; the sun shines, a refreshing breeze is sporting in the foliage spread out before my window ; I hear in the distance the rolling of carriages, and a child's trumpet which grates on my ears,—but is not all this a part of my dream ? Does not M. Radestock himself say, and I have underlined the words, that *in most cases* we can distinguish imaginations from real images ? There are then some cases in which we cannot : am I not in one of these cases ? And if this presents itself even once, how can I be sure that it is not always presenting itself ? In a note which ought to have figured in the text M. Radestock speaks of a Polish student whom he had met in a scientific society. This student used to be a somnambulist, and at the present time it often happens that in his dream he is conscious that all that he dreams is untrue, and still the false images do not go away. I have known some madmen who were in the same position. How is this possible ? What is it but a consciousness of reality ? I repeat it, we may to a certain extent consider that M. Radestock has said all that needed to be said, but I should have wished for a more detailed, more vigorous, and more profound analysis on this special point.

I shall have to point out again in the ninth chapter this same lack of depth. I say nothing of the seventh and eighth chapters, in which he treats principally of somnambulism, and of the differences in dreams, because this would lead me too far. In the chapter now to be considered, the author compares dreams with madness. "Madness is a waking dream," says Kant. The author does scarcely anything but comment on this definition ; he gives himself up to his taste for descriptions, in which he generally succeeds well ; but unfortunately, he makes use of too many figures, metaphors, and comparisons, which have their charms, but are wanting in solidity. The comparison should render the explanation clear and powerful, and not take its place. Between comparisons, then, and descriptions, and descriptions and comparisons, M. Radestock has reached a point where, by making me see resemblances and analogies, he has so confused and mixed up things that I cannot tell the difference between the man who is asleep and dreaming and the madman. However, no one is deceived : the madman is neither a sleeper nor a somnambulist.

The same remark applies to the last chapter, in which he treats of reverie and musings.

The author formulates his conclusion thus : "It is by degrees numerous, but still continuous and indivisible, that waking-consciousness passes into the consciousness of sleep and of dreaming, and between health and disease of mind we do not find a well-defined line, but there exists a great intermediate domain of troubles and disorders. No one could say exactly where reason ends and mental derangement begins."

Very well, but my whole being revolts from this conclusion, which confuses everything, and which in its final analysis suppresses reason and drives it from the universe. From the fact that there are intermediates between two opposite states, it does not follow that the one is the other : between the curve and the straight line there are all possible transitions, but there is only one straight line ; between

zero and unity there is every imaginable value, but none of them is zero or unity.

IV.

M. Stricker, whose ideas I am now about to expound, has, so far as I am aware, hitherto produced no work on psychology, and even the chapters which form the concluding part of his "Lessons on Pathology" will to some readers seem a mere digression. But we certainly may congratulate ourselves on the learned professor's having incurred the reproach of breaking the rule of unity of subject. I have rarely had the pleasure of reading any pages more lively, clearer, and more original on subjects which are somewhat trite. Like Spinoza, Traube, and Helmholtz, M. Stricker is a Jew: if I mention this it is because he does not write like most Germans; his style is rapid and condensed, his language short and incisive, his thought clear and piercing; I may add that his penetration is subtle and ingenious. I shall follow in my *résumé* the order of the master's lessons.

We must distinguish between *potential* knowledge and *actual* or *active* knowledge (*das lebendige Wissen*). At any given moment of my existence I can think of only a very small portion of all that I know: what I think of is actual knowledge; the rest belongs to potential knowledge. Actual knowledge is present to our consciousness, this latter word being used in its narrow and limited meaning. What is the seat of consciousness? This is a question which cannot be solved, and is in part needless: it is enough that it is universally admitted that the functions of the mind are dependent on those of the brain. It is now a matter of dispute whether it is the cell only that works psychically, and the nerves uniting the ganglion-cells act only physically, *i.e.* simply as instruments for transmission. However, when a deaf and dumb man pulls the bell, and his blind companion hears it, neither of them will be able to say that the *bell has rung*, in the sense which an ordinary man attributes to that phrase. Does not this comparison clearly show the impossibility of admitting the insulation of the psychical centres?

I attribute to others a consciousness like my own. This is not an *unconscious* judgment; this belief is explained quite simply by an association of ideas: when I see a piece of furniture in the shape of a cupboard I suspect that it contains a cavity, although I have never consciously formulated the conclusion that every cupboard is hollow.

Our ideas come to us primarily from experience, and secondarily from memory. Why do we refer the cause of our impressions to something external? By a result of habit; there cannot here be any question of innate idea: if a man had for many years always worn a cap, and if after taking it off he still felt it, should we talk of an innate idea?
